## **Preface**

### **Dear Conference Participants!**

The conference “Finance and Performance of Firms in Science, Education and Practice” creates the possibility for gathering and exchange of knowledge and experience of all those, who are actively engaged in this area: researchers, representatives of companies, banks, insurance companies and other financial institutions, public administration as well as PhD students. After successful conferences held in previous years, the Faculty of Management and Economics of the Tomas Bata University in Zlín has decided to organize already the seventh annual conference in order to again create a platform for professional discussions and dialogues of participants from different countries.

The programme of the conference, as well as the proceedings you have received, confirm that all these subjects and relevant problems are covered and that there is an opportunity for exchange of ideas and opinions. On the basis of double blind reviews, only papers that met the requirements of reviewers regarding the content, structure, and the completeness of the references cited were included in the Conference Proceedings.

Based on the good experience from previous years, this year again the conference programme includes contributions presented by economists from academic, public and private spheres; this creates a bridge between theoretical knowledge and practical experience in the area of finance and management of performance of organizations.

I hope that the course of the conference, the opportunity of personal contacts, exchange of knowledge and experience as well as information contained in the proceedings will contribute to the enrichment of understanding of the given set of current problems and to the support of further growth of cooperation.

***prof. Dr. Ing. Drahomíra Pavelková***

Zlín, April 2015

## List of Papers

Export Barriers and Export Performance Seafood into International Markets <i>Ai Tran Huu, Hau Tran Van</i>	16
Performance Management and Measurement of Enterprises: A Theoretical and Empirical Study <i>Alhassan Dawuda, Chromjaková Felicita</i>	33
Segment over 55 Years Old as a New Challenge for the Czech Companies <i>Barešová Petra, Staňková Pavla</i>	48
Impact of Allowed Debt Relief of Individuals in 2009 - 2014 on Current Satisfaction of Creditors <i>Bařinová Dagmar, Pinter Vojtěch, Branžovská Kateřina</i>	60
Selected Aspects of Quality of Business Environment in Segment SME. A Case Study from Slovakia <i>Belás Jaroslav, Bilan Yuriy, Novák Petr, Sipko Juraj</i>	68
Creative Industries and the EU Regional Policy: A Spatial Analysis of Using Structural Funds <i>Bednář Pavel, Danko Lukáš, Smékalová Lenka</i>	81
Competitiveness of Banking Institutions in the Context of Human Resource Management and the Concept of Corporate Social Responsibility <i>Bejtkovský Jiří, Vydrová Janka</i>	97
Students' Attitude towards Taking Risk and Starting Up Business within the Context of the Source of Received Income <i>Bernat Tomasz, Gasiór Aleksandra, Nagaj Rafał, Szkudlarek Piotr, Zakrzewska Malgorzata</i>	110
The Analysis of Dependence FDI Flows on the Size of Corporate Income Tax Rates in EU Countries <i>Blechová Beáta</i>	124
Customer Audit as an Important Tool Stimulating Company Growth <i>Briš Petr, Klímek Petr</i>	137
Do Investors Herd in Frontier Stock Markets? Empirical Evidence from Vietnamese Stock Market <i>Bui Duc Nha, Nguyen Thi Bich Loan, Nguyen Thi Tuyet Nhung</i>	146
The Economic Value Added Algorithm Risks in the Context of Corporate Performance Measurement System <i>Burešová Veronika, Dvořáková Lilia</i>	163
Models Predicting Financial Distress and their Accuracy in the Case of Construction Industry in the Czech Republic <i>Čámská Dagmar</i>	178

An Analysis of the Similarity of Selected Banks in Central and Eastern Europe <i>Černohorská Liběna, Kořátková Stránská Pavla</i>	191
Stock-Market Efficiency in Emerging Markets: Evidence from Vietnamese Stock Market <i>Do Thi Thanh Nhan, Le Tuan Bach, Nguyen Thanh Trung</i>	204
Life Insurance and the Role of Financial Arbitrator for the Resolution of Disputes within Life Insurance <i>Ducháčková Eva, Schlossberger Otakar</i>	217
Developing Supporting Industries through Building Industrial Clusters in Vietnam <i>Dung Vu Tri, Huyen Pham Thi</i>	232
How Strong Position Hold the IFRS in the Worldwide Financial Reporting? <i>Dvořák Martin, Vašek Libor</i>	244
The Improvement of Human Resource Controlling in Selected Service Companies <i>Ďugelová Monika, Strenitzerová Mariana</i>	258
Determinants of Innovation in Small and Medium Enterprises <i>Ehrenberger Marek, Lisin Evgeny, Strielkowski Wadim</i>	274
Depreciation Influence of Fixed Assets on Accounting Result and Corporate Income Tax Base Pursuant Accounting and Tax Legislation in the Slovak Republic <i>Ferenci Váňová Alexandra, Krajčířová Renáta, Váryová Ivana, Košovská Iveta</i>	287
Sovereign Wealth Funds: Wealth, Assets and Reserves <i>Ficová Antonia, Sipko Juraj</i>	297
The Dependence of Additional Purchasing of Banking Products or Services on the Loyalty of Banking Customers in the Czech Republic <i>Gabčová Lenka, Chocholáková Anna</i>	310
Efficiency of Czech and Slovak Insurance Companies Evaluated by DEA Models <i>Grmanová Eva</i>	319
Comparison of Czech and Slovak Public Administration Approach to the Concept of EU Cohesion Policy Implementation for the Programming Period 2014-2020 <i>Hájek Oldřich, Smékalová Lenka</i>	330
Research and Development Expenditure Assessment Based on Selected Indicators in the EU Countries <i>Halásková Martina, Halásková Renáta</i>	342
Public Sector Efficiency Analysis - Issues and Perspectives <i>Hamerníková Bojka, Maaytová Alena</i>	358
Multi-Criteria Analysis for the Most Efficient Selection of Bank Account for Young People <i>Hedvičáková Martina, Pozdilková Alena</i>	370
Regulatory Capital Requirement under BASEL, the Ability to Perform of Vietnamese Commercial Banks <i>Ho Thanh Tung</i>	385

Subsample Analysis in Structural Equation Modelling Example from Customer Satisfaction Modelling in Banking Industry <i>Homolka Lubor, Belás Jaroslav, Doležal Jiří</i>	400
Plastics Cluster Members and their Competitors - DEA Benchmarking Study <i>Homolka Lubor, Knápková Adriana, Pavelková Drahomíra</i>	409
Social Responsibility and its Importance to the Performance Management of Business Companies: Actual Situation in the Czech Republic <i>Hornungová Jana, Pavláková Dočekalová Marie</i>	416
Measuring Success of Mergers and Acquisitions and Common Mistakes to Avoid <i>Hudák Martin, Neumannová Anna</i>	431
Assessment and Evaluation of the Impact of Financial Risk on Small and Medium-Sized Enterprises in Slovakia <i>Hudáková Mária, Buganová Katarína, Dvorský Ján</i>	442
Creating Mobility of Residents on an Example of Medium-Sized Cities in Poland <i>Cheba Katarzyna, Kiba-Janiak Maja, Saniuk Sebastian, Witkowski Krzysztof</i>	452
How Do Women and Men Feel Some Aspects of Satisfaction and Loyalty in Banking Sector? A Case Study from the Czech Republic <i>Chocholáková Anna, Gabčová Lenka</i>	465
Saving Versus Investing in the Long Term <i>Chovancová Božena, Arendáš Peter</i>	475
Capital Structure Determinants and Human Capital: Pooled, Panel and Dynamic Panel Estimations <i>Jahanzeb Agha, Bajuri Hafiz Norkhairul, Ghori Aisha</i>	485
Evaluation of Investment Strategies Created by Multiobjective Genetic Programming <i>Jakubéci Martin</i>	498
Philanthropy in Terms of Tax Policy in the Czech Republic <i>Janoušková Jana</i>	510
Economic Growth and Innovation: Measurable Indicators of Economic Performance <i>Juříčková Eva, Hrušecká Denisa</i>	522
Mobile Banking in the Corporate Segment of the Czech Banking Sector <i>Kameníková Blanka</i>	533
The Exchange Interventions as a Tool of the Central Bank against Deflation in the Czech Republic <i>Kameníková Blanka, Nevřalová Vanda</i>	545
The Comparison of Level of Financial Literacy in Four Countries <i>Kantnerová Liběna</i>	559
Are the Bankruptcy Predictors Specific for a Given Time or Branch? The Evidence from the Czech Manufacturing and Construction Companies <i>Karas Michal, Režňáková Mária</i>	571
Banks from the Societe Generale Group and their Sensitivity to the Bank Run <i>Klepková Vodová Pavla</i>	584

Practical Use of the Box-Jenkins Methodology for Seasonal Financial Data Prediction <i>Klímek Petr</i>	598
Current Trends in the Factoring Market in the World and in the Slovak Republic <i>Koišová Eva, Ivanová Eva</i>	612
Analysis of Czech Companies' Departures to Tax Havens and their Effect on Czech Economy <i>Kolářová Eva, Kuderová Eva</i>	623
Philanthropy as Part of the Regional Context for Social Inclusion <i>Kolibová Helena, Chmelařová Magdalena</i>	638

## **EXPORT BARRIERS AND EXPORT PERFORMANCE SEAFOOD INTO INTERNATIONAL MARKETS**

*Ai Tran Huu, Hau Tran Van*

### **Abstract**

The purpose of this paper is to identify main export barriers and to test empirically their impact their on export performance of seafood firms, Vietnam, targeting the U.S market. Reviewing the literature and using expert opinions, 5 factors of the export barrier were identified. A structured questionnaire was applied to survey managers of 152 seafood firms and exploratory and confirmatory factor analyses were used to categorize variables in 5 the barrier dimensions. Then, a structural equation model was developed to determine which dimension has a greater negative effect on export performance. This model identifies the export barrier of products dimension (- 0.168), the barrier of price dimension (- 0.130), the barrier of distribution dimension (- 0.222), the barrier of promotion dimension (+ 0.101) and logistic dimension have a significant negative impact on export performance (- 0.156) have a effective export barriers to the export performance of seafood. Based on the relative importance of the different marketing barriers, seafood firms should firstly focus on quality improvements in order to improve their export performance.

*Keywords: Export barriers, Export performance, Seafood industry, Vietnam.*

JEL Classification: M11, F15, O19.

### **1 INTRODUCTION**

The structure of the seafood industry has changed significantly in recent years as changes in technology have promoted globalization in the industry. Technological advances in communication and transportation have reduced transaction costs, improving the ease of access to markets around the world. Consequently, international trade in seafood increased first by 25% in the 2000s, followed by a significant global trade boom of 50% growth from 2000 to 2013. Over 60% of that growth is contributed to market access in developing countries (Gehlher and Dohlman, 2009).

Export as an important economic activity to a firm and a driver of economic development of a nation has widely been acknowledged. In spite of numerous benefits of exporting, most firms do not export despite exporting being considered as inevitable in the increasingly integrated world markets (Papadopoulos & Martins, 2010), although the benefits derived from exporting in an increasingly globalized marketplace, for many smaller-sized manufacturers the internationalization path is beset by numerous obstacles. In particular, marketing barriers, such as product, price, distribution, promotion, and logistics, occupy an important position because they often cause financial losses and negative attitudes towards international activities (Leonidou, 2002; Balabanis, 2000).

The key role of exporting in national economies has resulted in export performance attracting considerable interest in many studies. Most research focuses on the relationships between performance and organizational or environmental factors; less has been done into the specific factors that could hinder exporting. The determinants of the export performance of small and medium-sized firms are of vital importance for policy makers, firm managers, and researchers (Baldauf et al., 2000; Katsikeas et al., 2000; Sousa et al., 2008). While most research focusing on export performance has been undertaken in the United States and Europe, limited work has been conducted in developing countries. Enhancing export performance is crucial for firms

based in developing countries that view the global marketplace as a means to ensure growth, survival or competitiveness (Matanda and Freeman, 2009).

## **2 LITERATURE REVIEW**

There is a growing block of literature on the impact of both globalisation and regional integration agreements on international business as well as on the issue of internationalisation of firms via exporting (Falbe & Welsh 1998; Pett & Wolff, 2000, 2003). Studies that identify problems firms face in exporting are scarce and relatively out dated and do not address the changing business environment as a result of increasing bilateral and regional trade agreements (Gripsrud, 1990; Ramaswami & Yang, 1990). The European Union (EU) and India are presently negotiating a free trade agreement (FTA), which aims to eliminate tariffs within a 7-year time frame with the target implementation date as 2010-11. Such an agreement could transform the overall business environment from the interconnectedness of these trading economies. Bilkey (1978) suggests that if trade agreements between countries and/or economic blocs are to achieve their potential and bestow benefits public policy may be required to help firms in overcoming export problems.

### **2.1 Export Performance**

Export performance has been a widely studied concept in international business literature (Shoham, 1999). Export performance both past and present are essential to the survival of the organization in diverse ways. Whereas past performance motivates managerial strategy actions, present performance signals the effectiveness of management strategy modifications as well as set forth new strategy actions, (Lages et al, 2008). There are many different perspectives on performance. The concept of performance has changed over time and expanded with the development of production management. In broad term, concept of performance can change depending on the scope of use (Tangent, 2005). Performance is also a theme that has been concerned by technicians, sociologists, economists and most managers for many years.

In technical aspect, efficiency is the ratio between output and input. It measures performance-using resources to produce the required output. However, this can lead to focus on quantity but little attention to quality aspects.

However, with the flurry of studies conducted over the years scholars are yet to generally agree on the conceptual as well as the operational definition of the concept. Operational definitions of export performance vary across the literature so far. Some scholars including Ahmed and Julian (2004) define export performance through export efficiency, export effectiveness and continuous engagement in export. Other scholars including (Koh, 1991 and Bilkey, 1982) define export performance through a construct that measures export intensity, perceived export profitability and continuous export activity. It is the latter construct that would form the basis of our measurement of export performance in latter chapters of this study. According to Shoham (1999) a conceptual definition of export performance should address two parts: export and performance.

Export performance is regarded as one of the key indicators of the success of a firm's operations. Research into export performance has grown considerably during the past few decades (Ibeh, 2008). While numerous studies have been conducted to explain export performance and its antecedents, there is no generally accepted conceptualization. Export performance represents the outcome of a firm's activities in export markets (Papadopoulos and Martin, 2010). Export performance can also be defined as the outcomes from the firm's international activities. From this perspective, export performance is the extent to which the firm achieves its objectives when exporting a product to a foreign market (Navarro et al., 2010).

## **2.2 Export Barriers**

Export barriers can be defined as the attitudinal, structural, operational and other constraints that hinder a firm's ability to initiate, develop or sustain international operations (Koksal and Kettaneh, 2011). It is important to achieve a better understanding of export barriers, since these barriers waste the resource of firms and threaten the efficiency and effectiveness of a firm's operations. The negative impact that export barriers can have on medium and small enterprises internationalization behaviors and activities has attracted the attention of many researchers in international business (Ortega, 2003; Da Silva and Da Rocha, 2001). Studies have employed different perspectives to establish a set of notable barriers, especially with regard to the specific industry or geographical area.

There are so many difficulties in foreign trade; some of them are as follow: 1- lack of awareness of export opportunities (data barrier), 2- managerial resource, 3- non-managerial human resources, 4- financial resources (investment), 5- production related barriers, 6- technical barriers, 7- competitive barriers, 8- distributive barriers, 9- official rituals and instructions, 10- payment barriers, 11- currency price barriers, 12- regulatory barriers (regulations), 13- governmental barriers and cultural barriers.

Leonidou has classified export barriers into two internal organizational barriers and external organizational barrier groups that affect the export activities of company. Studies show that, internal barriers are as management related difficulties, distribution problem, and problems related to the documents, lack of knowledge, social cultural and managerial factors. On the other hand, external barriers rooted on the environments outside of the exporter companies (Leonidou, 2004, Testom and Lutz, 2006).

Results of various studies showed that exporters' sensitivity to the barriers of foreign markets is determined through managerial perception that in its turn is affected by underlying factors in relation to the size, resource, and capability of company and its partnership in export and its international analysis (Barney, 1991; Suarez, 2003 & Ojal, 2007). Also researches show that exporters consider high bank profits, use of low potentials, and weak technology as big problems that affect their business performance (Frimpong and Mmeh, 2007:74-76). In general conditions, changes in consumers' preferences, the existence of brokers and agents, import tariffs, the risk of losing money in foreign markets, safety and quality standards, are other barriers to exports of companies (Rabino, 1980; Korth 1991).

## **3 THE RESEARCH RELATED TO MARKETING BARRIERS**

Marketing barriers refer to obstacles in the firm's overseas activities, such as product quality, price, distribution, logistics, and promotion (Karelakis et al., 2008; Sousa and Bradley, 2008). The overall review in Table 1 shows a comprehensive picture of the effects of those marketing barriers on export performance.

Tab. 1 - The Literature Review of the Effect of Marketing Barriers on Export Performance.

Notes: \* Reversed scale; M: multiple industries; O: one industry.

Generally, marketing barriers have been found to affect export performance negatively in most previous studies. Technical barriers to trade (TBTs) exist in most industries but are particularly widespread in the international exchange of primary and processed agricultural and aquaculture products. Recently, a considerable number of Vietnamese seafood products have been rejected at U.S. ports because they failed to comply with U.S. regulations on environmental amenities, food safety, and so on, causing significant losses to Vietnamese producers and exporters. This paper discusses TBTs that have been applied to Vietnam's seafood products as a means of import restriction. The paper also evaluates the effects of marketing barriers on Vietnamese seafood exported to the U.S. market. The resolution of this problem will contribute to the Vietnamese business community, assisting them to expand the volume of its trade with the U.S and gain a solid foothold in this important market. However, empirical evidence has often been found using data from multiple industries and investigating mostly one, two, or three kinds of marketing barriers.

The product barrier occurs in developing new products for foreign markets, meeting export product quality standards, adapting export product design/styles, and providing an after-sales service (Kaleka and Katsikeas, 1995; Leonidou, 2000, 2004). Small and medium-sized firms often lack managerial expertise, research skills, R&D competence, and financial resources, thus limiting the firms' fulfillment of the high-quality standards for products required by foreign markets (Leonidou, 2004). Different facets of the product barrier have been found to impact differently on export performance. Some facets have a very low impact (e.g., developing new products for foreign markets), while others have a low (e.g., meeting export product quality standards) to moderate influence (e.g., providing a technical/after-sales service) on export performance (see Leonidou, 2004 for a review). Generally, the relative role of product barriers is the weakest among the marketing barriers to the export performance of small and medium-sized firms across industries (Leonidou, 2004).

The price barrier involves offering satisfactory prices to customers and the difficulty in matching competitors' prices and granting credit facilities to foreign customers (Kedia and Chhokar, 1986; Moini, 1998; Leonidou, 2004). Small and medium-sized firms often suffer

high costs due to the lack of economies of scale, causing them to face difficulties in controlling their exporting operations. The aspects of the price barrier are documented to have a high to very high impact on export performance across industries, and among the marketing barriers, it is the strongest predictor of export performance (Leonidou, 2004).

The distribution barrier refers to complex foreign distribution channels, accessing export distribution channels, obtaining reliable foreign representation and maintaining control over foreign middlemen, and facing difficulties in supplying inventory abroad (Leonidou, 1995; 2004). The complexity and length of foreign distribution channels makes it difficult for firms to enter international markets. Small and medium-sized firms face a very low to a high impact of the different facets of the distribution barrier on their export performance. For example, while accessing export distribution channels and obtaining reliable foreign representation have a high influence, maintaining control over foreign middlemen has only a very small effect on export performance (Leonidou, 2004).

The logistics barrier is considered as an extensive dimension of the distribution barrier (Kaleka and Katsikeas, 1995; Yeung, 2006). The logistics barrier reflects the difficulties in supplying inventory in overseas markets, unavailable foreign warehousing facilities, and excessive transportation and insurance costs (Kaynak and Kothari, 1984). The lack of financial and human resources and a large geographical distance generate many problems for the firms in delivering products on time as well as maintaining the reasonable storage of products abroad. Most small and medium-sized firms feel that the excessive transportation/insurance costs are a major problem, while supplying inventory and warehousing facilities abroad is popular but relatively weak (Leonidou, 2004).

The promotion barrier, finally, deals with adjusting export promotional activities to individual foreign market requirements in relation to the variations in buying motives, consumption patterns, and government regulations (Howard and Borgia, 1990; Leonidou, 2004). The lack of resources and geographical distance also generate difficulties in adjusting export promotional activities. However, the effect of the promotion barrier on export performance for small and medium-sized firms is at a moderate level (Leonidou, 2004).

#### **4 THEORETICAL MODELS AND HYPOTHESES**

Tab. 2 - Measures of the variables in the model proposal. Source: Measures reviewed by the authors

<b>Measures</b>	<b>Measures review</b>
The product barrier	Howard and Borgia, 1990; Kaleka and Katsikeas, 1995; Leonidou, 2000, 2004.
The price barrier	Barrett and Wilkinson, 1985; Kedia and Chhokar, 1986; Keng and Juian, 1989; Moini, 1997; Leonidou, 2004.
The distribution barrier	Bauerschmidt et al., 1985; Keng and Juian, 1989; Leonidou, 1995, 2004.
The logistics barrier	Kaynak and Kothari, 1984; Barrett and Wilkinson, 1985; Leonidou, 2004.
The promotion barrier	Sullivan and Bauerschmidt, 1989; Howard and Borgia, 1990; Leonidou, 2004.
Enterprise Performance	Zou et al., 1998; Aaby and Slater, 1989 and Piercy et al., 1998; Jorge Carneiro, 2011.

Based on the above discussions, this study explores whether different categories of marketing barriers (product, price, distribution, logistics, and promotion) influence export performance

simultaneously in the context of one industry. Because different industries have different success factors and drivers of export performance (Leonidou, 2004), a comparison within one specific industry can be more reliable for the firms or managers within this industry. The following hypotheses are suggested:

*H1: The product barrier has a negative effect on export performance.*

*H2: The price barrier has a negative effect on export performance.*

*H3: The distribution barrier has a negative effect on export performance.*

*H4: The logistics barrier has a negative effect on export performance.*

*H5: The promotion barrier has a negative effect on export performance.*

In order to prioritize the different categories of marketing strategies, it is important to gain an insight into the relative role of those marketing barriers in export performance for a specific industry (Leonidou, 2004). This study expects that the price barrier has the strongest impact, then distribution, logistics, promotion, and finally the product barrier with the weakest impact on export performance. The theoretical model is shown in the figure below (Fig. 1).

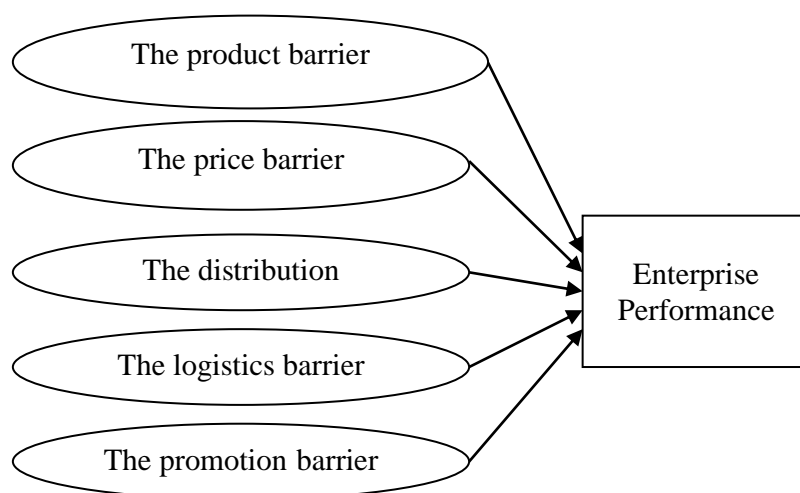

Fig. 1: Theoretical model. Source: Research results by author

Scales of variables are adjusted to suit the conditions of the VN seafood exporters based on in-depth interviews of experts and business managers.

Theoretical models have five independent variables measured by 24 observed variables and one dependent variable measured by four observed variables. Result measurement model is applied for all scale variables to access Cronbach's alpha coefficients.

Scale of the product barrier (S1) is measured by six observed variables, whose content refers to how developing new products for foreign markets.

Scale of the price barrier (S2) is measured by four observed variables, whose content refer to how offering satisfactory prices to customers and the difficulty in matching competitors' prices.

Scale of the distribution barrier (S3) is measured by five variables, whose content refers to complex foreign distribution channels, accessing export distribution channels.

Scale of the logistics barrier (S4) is measured by five variables, whose content refer to how extensive dimension of the distribution barrier.

Scale of the promotion barrier (S5) is measured by four observed concepts, whose content refer to deals with adjusting export promotional activities to foreign markets.

Scale of Enterprise Performance (F) includes levels where companies meet customer requirements of product quality measured by four observed concepts, whose content mention to how companies provide customers with quality products satisfying their requirements.

Export performance is regarded as one of the key indicators of the success of a firm's operations. Export performance can also be defined as the outcomes from the firm's exporting products to a foreign market (Navarro et al., 2010).

## **5 METHODOLOGY**

- ***Procedure for data collection***

This study aimed to investigate the relationship between export barriers and export performance in the commercial relationship of seafood firms, Vietnam, targeting the U.S market. Based on the aim of the study, an empirical analysis was conducted of Vietnam firms that target US as the market for their products. Since the majority of studies about international business and export performance have been conducted in the USA and Europe, there is a need for studies from developing countries to improve their poor export performance. On the other hand, with regard to volume of bilateral trade, Vietnam is a significant commercial partner for US in the ASEAN. Trade between Vietnam and US shows significant fluctuations in the trade balance.

Thus, focusing on this industry is expected to generate a comprehensive view of the role of marketing barriers in export performance in Vietnam. Seafood companies operate along all the coastal provinces in Vietnam with exporting markets covering over 165 nations and geographical areas. In preparation for this study, we focused on three key exported products: pangasius, shrimp, and surimi. About 200 seafood companies fulfilled the criteria and operate mainly in the south of Vietnam.

Quantitative research methods are used in this study. Theoretical models have five independent concept measured by 25 observed concepts and one dependent concept measured by three observed concept. Scale concepts studied in theoretical models are multivariate scale. The observed concepts are measured on a 5-point Likert scale (1: strongly disagree to 5: strongly agree). To ensure that the questionnaire's content and design would be unambiguously understood by the respondents, it was pre-tested by 12 experts (Four academic professors in the international business field, four consultants in exporting and international business and four managers of respected exporting firms in Vietnam) and the questionnaire was revised in light of their comments. The questionnaire was then mailed to managers of these firms.

A survey questionnaire was sent by e-mail to the business managers of 200 seafood companies with labour numbers over 300. We decided to ignore about 30 companies with fewer than 300 employees, as their sizes are too small to contribute significantly to the export activities, especially due to the labour intensity of the industry. In order to increase the response ratio, the firms' managers were contacted by phone to confirm their participation in the survey. Of the 200 questionnaires dispatched, 152 usable responses were received, representing an effective response rate of 76%. Statistical analyses were done in two phases; first an explanatory factor analysis was performed and then a structural equation model employed to determine which barrier groups have a greater effect on export performance. SPSS 22.0 and were used as statistical software for analyses.

- ***Description of the Survey***

The data collected from 152 seafood exporters in Vietnam with the characteristics are presented in Tab. 3.

Tab. 3 - Characteristics of the sample seafood exporters in Vietnam. Source: Data analysis of research data by SPSS 22.0

<b>Ownership</b>	<b>Quantity</b>	<b>Percentage</b>
Stock enterprises	64	42.11
Private enterprises	88	57.89
<b>Size</b>	<b>Quantity</b>	<b>100.00</b>
300 < Firm < 500	84	55.26
Up 500	68	44.74
<b>Total</b>	<b>152</b>	<b>100.00</b>

- **Reliability and Validity**

First, statistical analysis to calculate both the factor analysis and the scale reliability analysis, before carrying out factor analyses, a reliability analysis for the scale was run through Cronbach's alpha. The reliability of the questionnaire was 0.775, which is in the acceptable range. So, scales of this study have a rather high level of internal consistency and are reliable. The concept scales of the study are preliminarily assessed and screened by EFA method and Cronbach Alpha coefficients for each component. Selection criteria are satisfied when concepts have correlation coefficients turn-total (item-total correlation) >0.30, Cronbach alpha coefficients > 0.60; system load factor (factor loading) >0.40; total variance extracted for  $\geq 50\%$  (Hair & CTG, 1998).

Tab. 4 - KMO, measure and Bartlett's test. Source: Data analysis of research data by SPSS 22.0

<b>KMO and Bartlett's Test</b>		
Kaiser-Meyer- Olkin Measure of Sampling Adequacy.		.793
Approx. Chi-Square		1209.111
Bartlett's Test of Sphericity	df	190
	Sig.	.000

The results of the EFA, summarized in Table 5, showed 24 variations observed in 5 components of the enterprise performance scale and retained 5 factors with 20 observed concepts. There are four items of excluded observed concepts: *the product barrier*<sup>6</sup>, *the price barrier*<sup>4</sup>, *the distribution barrier*<sup>4</sup> and *the distribution barrier*<sup>5</sup>.

After excluding the four concepts, the EFA results 5 factors of enterprise scale. As KMO coefficient = 0.793, EFA matches the data and the statistical test Chi-square Bertlett 1209.111 worth 0.000 significance level. Thus, the observed concepts are correlated with each other considering the overall scope. The variance extracted by 64.903 shows that factors derived from 64.903% explained variance of the data, eigenvalues in the system by 1.247. Therefore, the scale draw is acceptable. The scales have observed concepts excluded by of EFA, Cronbach Alpha coefficients were recalculated, and the results achieved reliability requirements.

Model	Variables	Cronbach's alpha	Variance (%)	Value
Product barrier (S1)	5	0.808	<b>64.903</b>	Satisfactory
Price barrier (S2)	3	0.801		
Distribution barrier (S3)	3	0.802		
Logistics barrier (S4)	5	0.875		
Promotion barrier (S5)	4	0.723		
Enterprise Performance (F)	4	0.779	<b>60.308</b>	

- *Analysis of the Correlation Matrix*

The first step of conducting linear regression analysis is to consider the linear correlation between all the concepts. That means to consider the overall relationship between each independent variable with the dependent variable, and between the independent concepts (Hoang Trong & Chu Nguyen Mong Ngoc, 2008).

Tab. 7 - The correlation coefficient between the components. Source: Data analysis of research data by SPSS 22.0

Constructs	Mean	S.D	1	2	3	4	5	6
1. Export performance	4.10	1.49	–					
2. Product barrier	3.88	1.29	-0.49**	–				

3. Price barrier	4.05	1.45	-0.02**	0.04**	–		
4. Distribution barrier	4.12	1.91	-0.68**	0.57**	0.05**	–	
5. Logistics barrier	3.72	1.39	0.07**	-0.56**	0.07**	0.97**	–
6. Promotion barrier	4.20	2.09	-0.04**	0.06**	-0.03**	0.09**	0.07**

Notes: Correlations in bold are significant at  $p < 0.05$ .

• **Regression Analysis**

The estimated results of the multiple regression model indicate a good fit with the data ( $F = 31.470$ ,  $p < 0.001$ ;  $R^2 = 50.2\%$ ; all  $VIF < 2.0$ ). The results of testing the effects of marketing on export performance are shown in Tab. 8. This study expected that the product, price, distribution, logistics, and promotion barriers, irrespectively, affect export performance negatively.

Tab .8 - The Effects of Marketing Barriers on Export Performance Source: Data analysis of research data by SPSS 22.0

Independent variable	Unstandardized Coefficients		Standardized Coefficients	t	Sig.	Collinearity Statistics	
	B	Std. Error	Beta			Tolerance	VIF
(Constant)	1.341	.440		3.047	.003		
Product barrier	-.112	.074	<b>-.108</b>	-1.513	<b>.032</b>	.651	1.535
Price barrier	-.327	.051	<b>-.130</b>	-2.527	<b>.039</b>	.993	1.007
Distribution barrier	-.219	.056	<b>-.222</b>	-2.348	<b>.028</b>	.858	1.166
Logistics barrier	-.451	.072	<b>-.156</b>	-4.097	<b>.000</b>	.633	1.579
Promotion barrier	.104	.063	.101	1.643	.103	.870	1.150

Notes: \*  $p < 0.05$ ; \*\*  $p < 0.01$ ; ns: non-significant; all  $VIF < 2.0$ ;  $R^2$  (export performance) = 50.2%;  $F = 31.470$ ,  $p < 0.001$ .

Table 8 shows that the dependent variable correlates have quite strong linear correlation in the sense  $\alpha > 0.05$  with five independent concepts S1, S2, S3, S4, and S5. Since all absolute correlation coefficients between the concepts are in range of 0.633 to 0.993 satisfying  $-1 \geq r \geq +1$ , all concepts satisfy the rule of multiple linear regressions.

This proves that the value achieved distinction in other words; the scales of this study measured the different variables of studies. Correlation matrix also shows that variables of distribution barrier have the strongest negative impact on the dependent variable of the enterprise performance. In contrast, promotion barrier has the least impact on the dependent variable of the enterprise performance.

From Table 8, show that all four factors S1, S2, S3 and S4 of scale factors affect export performance, have a negative impact on export performance (F) at the means  $Sig = 0000-0039 < 0.05$ . The remaining factors S5 ( $Sig = .101$ ), there is no statistically significant. Thus, researchers can conclude that the hypothesis H1 (S1), H2 (S2), H3 (S3), and H4 (S4) are accepted. The regression equation for the normalized variable coefficient takes the following form:

$$F1 = -0.108 X1 - 0.130X2 - 0.222X3 - 0.156X4 + 0.101X5 + \epsilon_i$$

Among them: F: Enterprise Performance (F)  
 Product barrier (S1)  
 Price barrier (S2)

Distribution barrier (S3)  
Logistics barrier (S4)  
Promotion barrier (S5)

Fig. 2 – Regression standardized residual. Source: Data analysis of research data by SPSS 22.0

- *Assuming normal distribution of residuals*

According to the analysis of the residue showed the average value  $1.70E^{-15}$  Mean =  $\sim 0$  and standard deviation Std. Dev = 0983  $\sim 1$  can distributed approximately standardized residuals. Therefore it can be concluded that the hypothesis of normal distribution model is not violated.

Normal P-P Plot of Regression Standardized Residual

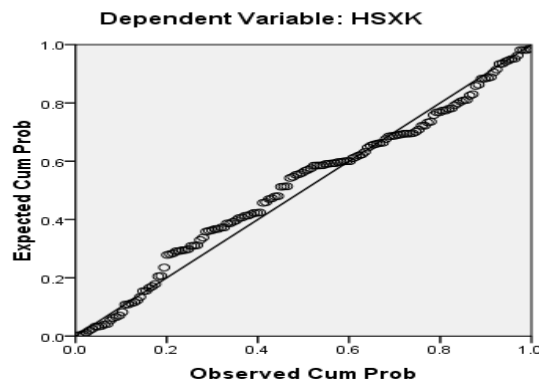

Fig. 3 – Normal P-P Plot of Regression standardized residual. Source: Data analysis of research data by SPSS 22.0

- **Assume contact linear**

Considering the relationship between standardized residuals and predicted values through scatter plots, assuming a linear contact and equal variance is satisfied there is no contact between the predicted value and the part balance, we will randomly distributed in a way around the vertical axis passing through the 0 and does not form a specific shape.

Fig. 4 – Regression standardized Predicted Value. Source: Data analysis of research data by SPSS 22.0

## 6 CONCLUSION

### 6.1 Results and Discussion

This study extended previous studies (Kaynak and Kothari, 1984; Leonidou, 2000) by analyzing and assessing the impact of trade barriers (product, price, distribution, logistics and promotion of export performance in a commercial industry homogeneous distribution and production environments. The study used data from the fishery industry of Vietnam, has inherited the previous studies, conducted mainly in the West.

- The results confirm the negative relationship between products barrier for export performance ( $\beta = -0.108$ , Sig = 0.032,  $t = -1.513$   $p < 0.05$ ). This result is consistent with most previous studies (Kaleka and Katsikes, 1995; Karelakis et al, 2008). However, whereas most previous studies here in the developed countries showed the importance of the product barriers is the weakest (Moini, 1998; Leonidou, 2004), this study confirmed the predicted barriers are the most important products for export performance of seafood companies in Vietnam.

Most seafood companies in Vietnam only export a few product lines, such as shrimp, fish, or crab, as frozen raw products. In particular, most products are sold through foreign middlemen, and not to the ultimate consumers. This limits the ability to develop new products for a specific foreign market's needs and wants, regardless of the diversity of consumer preferences across countries. In addition, although the production of high-value-added products is encouraged and aided by the Government, many firm seem to be afraid of the risks due to the lack of international market understanding.

- The findings show a negative effect of the price barrier on export performance ( $\beta = -0.130$ , Sig = 0.039,  $t = -2.527$ ,  $p < 0.05$ ). This result is similar to those of most previous studies (Moini, 1998; Leonidou, 2000). The price barrier is also found to be the second most important predictor of export performance in the industry. Although

most seafood firms in Vietnam take advantage of the low labour cost, the price barrier is becoming more serious due to increasingly scarce materials and a polluted environment.

- The present results also confirm a negative relationship between the distribution barrier and export performance ( $\beta = -0.222$ , Sig = 0.028,  $t = -2.348$ ,  $p < 0.05$ ). This result is consistent with most previous studies (Leonidou, 2002; Moini, 1998). Although the distribution barrier's impact on export performance is weaker than that of the product and price barriers in the industry, the magnitude of its effect is relatively strong. In fact, most export markets in the seafood industry are in developed countries. Therefore, the firms have to face distribution channels consisting of many layers, direct distribution systems, and the diversity of the services required by distribution members across countries (Leonidou, 1995, 2000). This complexity of the distribution systems creates serious difficulties for the firms.
- The findings also reveal a negative effect of the logistics barrier on export performance ( $\beta = -0.156$ , Sig= 0.000,  $t = -4.097$ ,  $p < 0.05$ ). This result is consistent with most previous studies (Katsikeas, 2008). Although the export revenue has continuously increased in recent years, the export markets of the firms focus mainly on the US, the EU, and Japan; the great geographical distance increases the transportation costs as well as limiting the ability to supply adequately. In addition, most firms have no warehousing facilities abroad. Thus, the flow of products to the host markets is not constant and is sometimes delayed. The characteristics of seafood products, which require special storage and faster transportation means, force the firms to pay extra costs. In most cases, the firms have to cover additional insurance, which increases the price of the products for the end-users. As a result, the logistics barrier can decrease the firms' competitiveness in international markets.

Finally, the results do not support a negative relationship between the promotion barrier and export performance ( $\beta = 0.101$ , Sig= 0.103,  $t = 1.643$ ,  $p > 0.10$ ). This result is inconsistent with most previous studies (Koksal, M.H. and Kettaneh, T., 2011). However, it is worth noticing that although the effect of the promotion barrier on export performance is not significant, the promotion barrier correlates highly with other marketing barriers. Thus, its effect on export performance may occur indirectly through other barriers, such as product, price, or distribution. As a result, it would be a mistake to ignore the role of the promotion barrier in export performance. In fact, not many seafood firms in Vietnam can carry out their promotion strategy abroad effectively. What we can observe is that only a few firms introduce their products at expo exhibitions, some have a website to advertise and provide limited information about their products, while most firms have no advertising activities in overseas markets due to high costs. These shortcomings generate risks for the firms when their export revenue is mainly based on a certain amount of familiar customers.

## **6.2 Implications for practical trading**

This study has implications for the management of commercial and industrial sector. First, the seafood company should pay attention to the various trade barriers based on the impact to reduce or improve export performance. Despite the importance of each type of barriers, as well as every aspect of every category, most of the aspects of trade barriers play a certain role in the export performance. This means that managers and traders should have a comprehensive view of the limitations of the barriers to trade mixed strategy of the company. A combination of tight link between the activities of the members of the company and build a mechanism for sharing information as well as the use of common resources can be a good solution to overcome institutional barriers to trade on the international market.

According to the study of the industry Vietnam seafood exports, enterprises should focus primarily on the barriers to product, price, distribution, logistics and promotion. More importantly, for each type of trade barriers, companies should determine the cause of each problem. For example, lack of knowledge and information about consumer attitudes, preferences, habits, may be the cause of the production does not meet the desired needs of the consumer. Thus, a survey of consumers in the target market can help solve this problem.

Finally, as mentioned in the introduction, the fisheries sectors plays a very important role in the economy, especially in providing jobs for the people and bring a large amount of foreign currency for the country. Thus, policy makers in the fisheries industry to support enterprises to minimize the negative impact of trade barriers. They should organize workshops or classes guide how to improve strategic commercial mixture of seafood exporters.

They can also help businesses by providing information on food safety standards, potential customers or how to enter a foreign market wants. Enhanced tools to encourage exports, such as financial assistance or consult experts and consultants to help businesses operate more efficiently export (Karelakis et al, 2008).

The first two objectives, to identify and evaluate product marketing opportunities including product specifications for potential exports, are through the survey data. In recent years, the Vietnamese seafood export industry has been exponentially increasing in value added agriculture and food products. The seafood industry in VN is already very active in international markets. A larger sample size which more accurately reflects seafood businesses would identify product marketing opportunities more specifically.

Regarding the objective to identify and evaluate transaction requirements for potential exports, the results indicate that high costs to exporting are perceived mainly by non-exporters. Few current exporters cited costs, exchange rates, or record keeping as constraints to exporting; rather trade barriers and tariffs were important to exporting firms. Transaction costs such as exchange rates did, however, play a role in the withdrawal of former export participants from international markets.

### **6.3 Policy Implications**

Export assistance and promotion programs are designed to increase the Vietnamese seafood export industry, and those programs have evolved to focus on encouraging exports among small to medium sized firms. From a firm perspective, the programs are designed to bridge information gaps about international markets and assist in the initial pursuit of international markets. Few studies have analyzed the efficiency of export promotion programs on the sustainability of exports among smaller businesses. Balabanis, G. I. (2000) found a positive correlation between the trade leads and export programs and a firm's self-proclaimed export success. The results of this research are useful for the policymakers in the design of the Vietnamese trade policy. Assistance programs for international marketing are available to seafood firms through the Vietnamese Directorate of fisheries and also through trade associations like the Vietnam Association of Seafood Exporters and Processors (VASEP).

Among participating current exporters, 63% did not use government assistance programs, stating that those programs were either not useful or the firm was unaware of such programs. Only one of the exporting firms used the Vietnamese Directorate of fisheries for export assistance. Further export research should include a cost benefit analysis of export promotion policies in the Vietnamese.

### **6.4 Suggestions for Further Research**

Currently, research pertaining to the international involvement of the Vietnamese seafood export industry is limited. Additional information in this area will help identify the needs of the Vietnamese seafood for potential exports and the overall perception in the industry about

international marketing. Further research will also benefit policymakers in the design of state export promotion and assistance programs. A more in-depth investigation is needed into the role of a firms' competitive advantage in international markets, and also into the conflict between export promotion programs and the "buy local, sell local" campaign.

Future studies would benefit from exploring other barriers (e.g. procedural, informational, or environmental) that affect export performance. The results presented here are based on self-reported measures of export performance relating to the Vietnamese seafood industry. Objective measures of export performance could be used to increase the generalizability of the study.

Increasing the sample size for this study, following survey sampling protocol, will permit a more thorough analysis with the inclusion of additional variables and theories. A mail survey might be more efficient at increasing the sample size and a comparison of response rates for different data collection methods among seafood businesses would be informative for researchers. The study could be enhanced using case study and interview approaches to gather more information about the Vietnamese seafood businesses and food processors.

## **PERFORMANCE MANAGEMENT AND MEASUREMENT OF ENTERPRISES: A THEORETICAL AND EMPIRICAL STUDY**

*Dawuda Alhassan, Felicita Chromjaková*

### **Abstract**

Research on performance management and measurement of enterprises has recently become a topic of importance to policy makers, media and academics alike. This field of performance management and measurement is rising quickly as respond to the roles of enterprises and companies changing and the global trends. Even though, much research has been developed in this field, there is no approved standpoint for an ideal framework in the literature for performance management and measurement. At the same time, theoretical and empirical evidence linking performance management and measurement is limited. Therefore, this study investigates theoretically and empirically performance management and measurement of small and medium-sized enterprises in the Czech Republic. It proceeds with relevant theoretical and empirical review of performance management and measurement. Then, this study discusses the impacts of performance management and measurement on Czech small and medium-sized enterprise performance. In order to fulfil these purposes, this study uses a case study approach.

*Keywords: Management, Measurement, Performance, Performance management, Performance measurement, small and medium-sized enterprises*

JEL Classification: H12, L25, M10, P17

## **1 INTRODUCTION**

Normally, the term “Performance” can be applied at these levels: personal, team or organization. One of the basic functions of management is managing and measuring performance. Also, in the management science, the two processes that cannot move apart from one another, as both proceeds and follows each other are the performance management and measurement. Moreover, the recent global financial crisis or economic recession has enforced policy makers, enterprises, companies and organizations to reassess their management structures and strategies. One of the growing responses to these expectations is the performance management and measurement as a control system. At the same time, governments, managers, public and private sector organizations and academics have recognized the importance to deploy and develop performance management and measurement to stay high performance. For example, one of the key systems the European Commission uses yearly to assess and check its member countries progress basis in implementing the Small Business Act (SBA) is the performance review of the small and medium-sized enterprises (SMEs).

The goal of this study is to assess, discuss and comment on the importance, challenges, limitations and benefit of performance management and performance measurement, as well as its linkage. For instance, in the Czech Republic SBA Fact Sheet 2014, it states that there existed many SME policy areas where action needed and where Czech performance fails to match with the European average. Though, this primarily concerns, responsive internationalization and administration, and all other areas in the year 2013 report showed

average performance. Hence, this partly explains why Czech SMEs performance remained weak.

The research problem of this study derives from the SBA Fact Sheet 2014. Therefore, this present research paper tries to find out why Czech SMEs performance is still weak? Then, what are the current problems and challenges facing Czech SMEs?

The structure of the research paper is as follows. Section two is the theoretical background of performance management and measurement. Next is a brief, relevant literature review of performance management and measurement. Section four is the research method and strategy. Then, the findings and discussion is the section five. Conclusion is the last section.

## **2 THEORETICAL BACKGROUND**

This section presents a brief theoretical background of performance management and measurement (in companies or organizations) using a maturity model of performance management and measurement – assessing organizational capabilities of performance management and measurement (Chelnicuic, 2010). Performance measurement is like a sub process of performance management, as (Brudan, 2010) highlights that; it concentrates primarily “on the identification, tracking and communication of performance results, by the use of performance indicators”.

### **2.1 Performance management maturity model**

According to (Klimko, 2001) a maturity model is a procedure that describes the progress of an entity over time and has the following four features, First, the development process draw by employing a few levels. Then, each level distinguishes from a certain need, which must get to pass to the next level. Third, the levels arrange sequentially, from the first up to the end level. Fourth, the development process takes progress from one level to the next. For example, Maslow Pyramid was one of the well-known examples of a maturity model. (Maslow 1943) argue that there is a hierarchy of human needs, starts from physiology to self-actualization needs and during the hierarchy that is all levels must achieve by ideally individuals. Though, similar adapted plans can apply to assess the progress of every entity, no matter of its form or nature. Such an entity could be present-day organization or SMEs or enterprises.

Management models aim to assess performance and find different opportunities for development of the organizations or enterprises or SMEs, as its main strategic tools for building capabilities and attain competitive advantages. In line with these, for example, in the United Kingdom, from the Office of Government Commerce (OGC UK 2008) specialists highlight that, maturity models have become important tools for assessing organization's capabilities which help in their activities to carry out change and develop in a structured way. According to the OGC, the reasons why organizations or enterprises might choose to use a maturity model to assess their capabilities; first, better understand of weaknesses and strengths to enable development to happen. Second, service quality recognition to support proposals, third is justifying investments in development processes, fourth is mapping for continual progression and development. Fifth is focusing on the organization's maturity and not precise initiatives. Figure 1 shows the performance management maturity model (PMMM a) and it is an academic research project result using different data sources such as, specialized literature in performance management and measurement review, highly acknowledged maturity models review and performance management practitioners' insights. According to (Chelnicuic, 2010), (Brudan, 2009) was the originator of the maturity model.

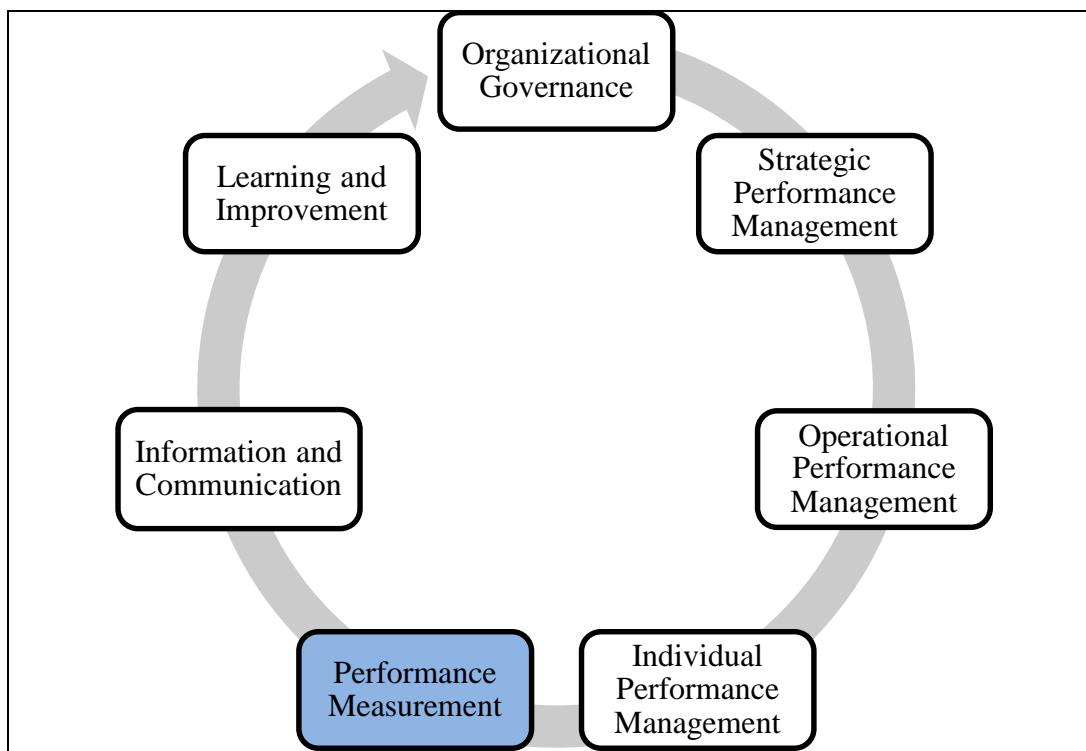

Fig. 1 – The (PMMM a). Source: Adapted from (Chelniciuc, 2010)

The performance management maturity model is built on seven steps each defining characteristics of performance management system. The maturity model for performance management also employs a five levels maturity framework (see table 1) adapted from Portfolio, Programme and Project Management Maturity Model (P3M3 Models, 2008) and The Capability Maturity Model Integration (CMMI, 2001). Therefore, organizations or enterprises or SMEs can assess the level of maturity of their performance management practices in each of these seven steps of the maturity model against the five levels maturity identified and described (in the appendix A).

Tab. 1 – The five maturity levels. Source: Adapted from (Chelniciuc, 2010)

Maturity Levels				
Level 1	Level 2	Level 3	Level 4	Level 5
<i>Ad – hoc</i>	<i>Beginner</i>	<i>Intermediate</i>	<i>Advanced</i>	<i>Proficient</i>

## 2.2 Performance measurement maturity model

The roles and importance of performance measurement; according to (Neely, 2002), commentators and researchers are discussing the several roles of measurement, as it acknowledges that performance measurement allows managers to do more than simply check improvement. Performance measurement system is a procedure supporting a constant learning in which feedback employ for making adjustments and identifying successes to agree upon initiatives or strategies to make sure continued excellence of services and activities, and to advance for the achievement of the organization's objectives, mission and vision. Performance measurement can also give a systematic and balanced attempt to evaluate the organizations' effectiveness operations from different viewpoints: business performance, employees, clients or customers and financial. In this situation, it is a must support performance measurement

system. Thus, to ensure that a mature and streamlined performance measurement practice is in place is to evaluate the present measurement capabilities against a “Performance Measurement Maturity Model” (see figure 2).

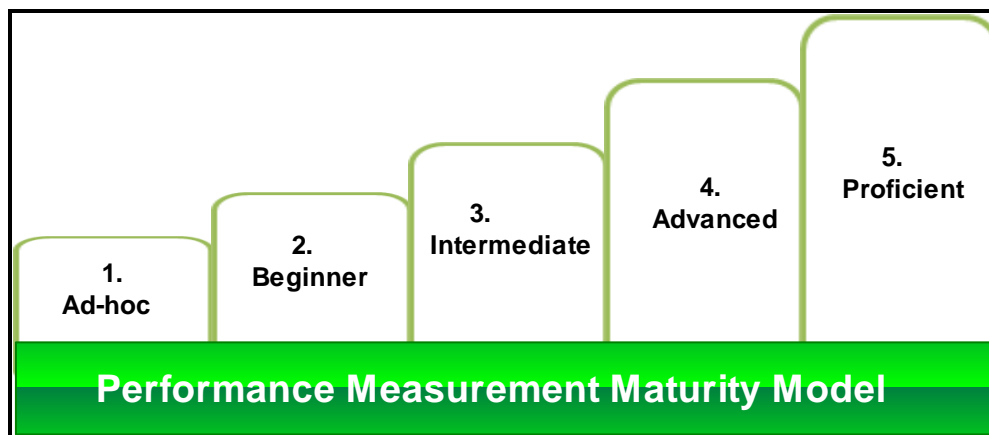

Fig. 2 – Performance measurement maturity. Source: Adapted from (Chelniciuc, 2010)

This model was also proposed by (Brudan, 2009) supported by experience obtained as implementers of Performance Management Systems and smartKPIs.com as developers, one of the finest repositories in the world with KPIs. Facts about maturity models; the major reasons why organization or enterprises might choose to employ a maturity model to assess their present capabilities are as follows: First, better understanding of weaknesses and strengths to enable development to happen. Second is the service quality recognition to support proposals. Third is justifying investments in the development process. Four, is mapping for continual progression and development. Five, is the focusing on the organization’s maturity rather than precise initiatives. Therefore, the maturity models demonstrate to be important implements to help SMEs or enterprises, or organizations guide their process maturity, processes to a common standard, following a step by step structured and predefined track. In addition, the performance measurement maturity model represents new implements that SMEs or enterprises or organizations can employ in evaluating the maturity of their performance measurement capability.

The performance measurement maturity model (PMMM b) is based on five dimensions (see figure 3) each describing the step or characteristic of it process (table 2).

#### ***The need of Performance management and measurement maturity model***

The following points are the summary of the performance management and measurement maturity model need. First is the organizational performance. Second is the organizational capability. The third need is the trained and motivated staff and the fourth is the having the right processes in place.

#### ***The benefits of using performance management and measurement maturity model***

The following points are the summary of the performance management and measurement maturity model potential benefits when organizations or enterprises are using as an assessment and review tool. First is the better understanding of weaknesses and strengths. Second is the basis of a roadmap for improvement. The third is the justifying investments. The fourth is the concentrating on the organization’s performance maturity and the fifth is the improving organizational performance.

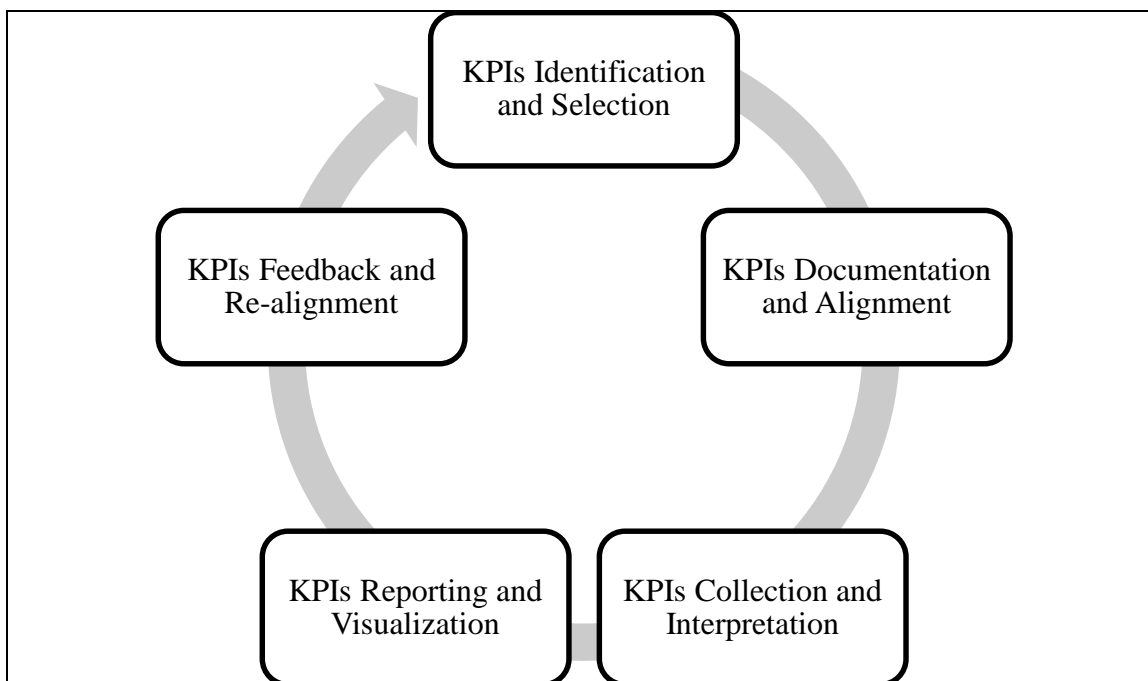

Fig. 3 – The (PMMM b) - Dimensions. Source: Adapted from (Chelniciuc, 2010)

Tab. 2 – Describing the step. Source: Adapted from (Chelniciuc, 2010)

<p>KPIs Identification and Selection – has an impact on the directions of organizational strategic. Indicators should focus on actions, services provided in order to achieve the organizational strategic objectives at each level. This must be considered at all times the measurement of what is important and not necessarily easy.</p>
<p>KPIs Documentation and Alignment – secures that the selected indicators are actionable, by establishing definitions, purpose, calculation formulas, targets, methods of data collection and reporting and data owners and custodians.</p>
<p>KPIs Collection and Interpretation – needs to be supported by a well-defined and optimized system solution that responds to the performance measurement collection needs of the organization. Responsible for data gathering must be identified and assured data availability for each KPI tracked in the Performance Scorecards and Dashboards.</p>
<p>KPIs Reporting and Visualization – regardless of the parties involved in the reporting process it must be assured that the process is effective and efficient. An inefficient and ineffective reporting system will not generate any positive effect on improving the performance of an organization. Data visualization is an important part of the measurement process, and this involves processing information with a graphic description of it in order to be understood and transmitted more easily, faster and more efficiently.</p>
<p>KPIs Feedback and Re-alignment – is one of the most important parts of the performance measurement cycle. It secures that the KPIs are kept on track and aligned with the organizational strategy, in order to provide with valuable information that will allow improved organizational practices.</p>

### **3 LITERATURE REVIEW**

This section presents a brief literature review of performance management and measurement, focusing on enterprises, SMEs, large companies or organizations and extended enterprise. Then, it talks about the linking of performance management and measurement for SMEs. Furthermore, the importance, challenges, limitations and benefit of performance management and measurement.

Researchers for example (Taticchi, et al., 2010) reported details literature review on performance management and measurement for large companies and SMEs. (Garengo, et al., 2005) are among the researchers to review the literature on performance measurement in SMEs manufacturing. (Hudson, et al., 2001) investigation focus on the development process of strategic performance measurement system for SMEs, by employing topology, survey and case study approaches. In contrast, (Bititci, et al. 2005) are among the investigators conducted research in extended enterprises. (Taticchi, et al., 2010) claim that, the review of the literature reveals a certain maturity relating to large companies and a significant lack for SMEs. Therefore, the evolution and development of this discipline are entering new directions, and these directions are by challenge, by context and by theme conceptualized. However, (Garengo, et al., 2005) described characteristics and the main factors influencing performance measurement in SMEs. Then, claimed that few companies or enterprises carry out performance management in SMEs. There are gaps between practice and theory, thus, little study focusing on performance measurement in SMEs is available. Besides, to introduce performance measurement in SMEs there are obstacles and these are endogenous barriers (short –term strategic planning) and exogenous barriers (financial and human resources). (Garengo, et al., 2005) get the conclusion that, only two researchers (Laitinen 1996, 2002; and Chennell et al., 2000) models exclusively concentrate on SMEs. Therefore, it is necessary to carry out further study of performance measurement systems in SMEs and large companies. (Hudson, et al., 2001) get the conclusions that, there is inadequate literature in respect of specific SMEs context, inadequate empirical evidence that describes the performance measurement practice in SMEs, as none of the SMEs studied had taken steps to update or redesign it performance measurement. There are barriers to the development of strategic performance measurement in SMEs such as strategically oriented and resource intensive. In addition, these issues are problematic because developing strategic performance measurement is a long term and requires measures should be focused. Alternatively, (Bititci, et al. 2005) studies how performance measurement may be embraced to manage and measure performance in extended enterprises. (Bititci, et al. 2005) claim that, due to structural differences between traditional and extended enterprises, performance measurement systems requires to manage and measure performance of extended enterprises, though being built upon existing performance measurement frameworks, would be operationally and structurally different. Therefore, from this, (Bititci, et al. 2005) proposed their model for managing and measuring performance in extended enterprises.

Lately, (Ahmed, and Sun, 2012) also developed a model to follow up, improvement and assessment for production performance management for SMEs in Sweden. At that point, (Peci, et al. 2012) employed case study with an unstructured questionnaire to study the impact of informal and formal factors on the development of SMEs in Kosovo. (Ahmed, and Sun, 2012) highlighted that, most frameworks are developed for large companies and SMEs lack effective performance management framework. (Ahmed, and Sun, 2012) model were based on literature study, and multiple case study was employed to check the applicability of the case study. Then, (Peci, et al. 2012) get the conclusion that, informal activities caused by low levels of professional, ethics of officials in institutions and poor enforcement of regulations

have significant impact on transaction costs, as these are obstacles to further growth for SMEs in Kosovo.

(Lukeš, 2013) use the innovative behaviour inventory with a total number of 3508 working populations of the Czech Republic, Germany, Switzerland and Italy. (Mohelská and Sokolová, 2014) study take a look at different forms of education in using e-learning for business disciplines. For example, (Kaňovská and Tomášková, 2014) employed a new method questionnaire, standard statistical methods and Cronbach alpha techniques to investigate the relationships between strategic behaviour and market orientation at the high-tech companies in the Czech Republic. (Lukeš, 2013) investigate whether entrepreneurs differ from managers in different areas of innovative behaviour at workplaces and whether this behaviour differs for entrepreneurs who have and do not have workers. (Lukeš, 2013) conclude that people in entrepreneurial activities, develop new ideas and try to overcome difficulties during implementation over employed people. Hence, these show that entrepreneurs' positions are high in attaining innovation outputs. (Mohelská and Sokolová, 2014) uses university students in the academic year 2009/10 and 2010/11 participating in the course Principle of Management, as their goals are to compare e-learning or training with the traditional training of employees. Mohelská and Sokolová, 2014) find out that both the e-learning and traditional way of training in basic managerial skills are the same as efficient. Then, (Kanovska and Tomaskova, 2014) find out that strategic behaviour is a part of market orientation. Therefore, strategic behaviour can be classified as decision making and methods of information. Thus, these influence business performance.

## **4 RESEARCH METHODOLOGY AND STRATEGY**

This section presents the research methodology and the use of scientific approaches and research strategy to ensure reliability and validity.

### **4.1 Scientific knowledge**

Academics claim that scientific knowledge is a knowledge acquired through scientific methods that are supported by sufficient validation. The following are the main factors to determine whether the facts or evidence are scientific knowledge. First, is testing. Second, a peer review and publication. Third, is the potential rate of error and the fourth, is the degree of acceptance among the scientific community. At the moment, competition in the globalization has also increased; the business environment has become a complex about the uncertainties of the market conditions. At the same time, organizations or companies or enterprises are facing challenges, and are willing to embrace the uncertainties of adopting the best practices, and this study provides these goals. For example, (Gray, 2013) claims that, SMEs needs to identify and adopt best practices so as to face the changing and complex business environment.

Therefore, this study is based on scientific knowledge and adopting an appropriate methodology. Thus, by implementing and identifying the best practices, uncertainties could be avoided in the study. These practices would be add-on to SMEs to compete with the current market conditions by managing and improving their performance in a scientific manner.

### **Scientific approach**

According to (Ghauri and Gronhaug, 2005) academics can embrace different approaches to research, such as abduction, deduction and induction. The deductive reasoning, (Zhang and Wu, 2010) claims it was built on logic, from generalization to precise cases. In the deductive

method hypothesis is tested and its lead to modification, approval or cancelation of principle. (Gray, 2013) argue that this process requires concepts or ideas to be measurable in order to make empirical research reject or validate the hypothesis. Thus, based on the empirical research the relationship between these concepts is checked. Inductive reasoning (Zhang and Wu, 2010) claim is a movement from precise cases to generalize and this could lead to discovery. (Gray, 2013) argue that in inductive method, the patterns of data collection are analyzed to review the relationships between variables and these lead to generalization even to theory development. However, deductive and inductive methods have many differences, for instance, structure of construction, data collection, generalization, and time duration and so on. (Lewis et al. 2007) highlight that the combination of deductive or inductive methods could be applied only when the implementation of these research methods cannot fulfil the requirement of research design. Then, the abductive method, (Dubois and Gadde, 2002) claimed that, it back to discover variables, relationships and new things. Thus, the abduction reasoning employs both the deduction and induction reasoning. Therefore, abduction method is the scientific approach employ in this study.

#### **4.2 Research strategy**

The research strategy employs in this study is a case study. A case study is described by (Thomas, 2010), as a focus rather than a method or procedure. Then, (Thomas, 2010) point out that, case study covers many methods to research. Besides, case study has the following questions that a researcher usually faced with; in the first place, what's the situation? Then, what's going on here? Next, what happens when? And the fourth what is related to what? Thus, case study can answer these questions. Furthermore, (Silver, 2013) identified three case studies, namely collective, instrumental and intrinsic. The collective case study is for building theories or studying general phenomenon and require investigate many cases. Then, the instrumental case study revises generalization or examines a case give inside of an issue. Lastly, the intrinsic case study solves problem with a single case.

A case study also gives a chance to accumulate data through different sources (Gray, 2013). This comprises structured and semi structured interviews, document analysis, possibility of conducting open, and filed observation. Moreover, (Thomas 2010) claims that, data collection of case studies makes the evidence and information built on data, but it leads to disapprove or approve of the proposal. Hence, structured planning of information collected for proposal makes the data collection as evidence for further research.

Tab. 3 – Thomas 2010 case study. Source: Adapted from (Thomas 2010)

Mainly use words	Use words, images and/or numbers	Mainly use numbers
<u>Interview</u> – Structured, -Unstructured, - Semi-structured	Questionnaires	Measurements and tests
Accounts	<u>Observation</u> – Structured observation, -Unstructured observation, -Participant observation	Official statistics
Diaries	Image – based methods	Other numerical data
Groups interviews		
Focus groups		
Interrogating documents		

Data assembling tools also back case study purpose. Table 3 above shows divergent approaches for collecting evidence. However, earlier scholar (Yin, 1989) had suggested that in case study there are three conditions that determine research type programme, these are firstly, the research question; secondly, researcher control possible; and thirdly, focus on contemporary events desired. Table 4 shows an outline of performance of each research strategy under each condition. Generally, a case study offers a better chance to research the phenomenon; hence the nature of case study employs in this research is instrumental and intrinsic case study.

Tab. 4 – Outline of performance of research strategy. Source: Adapted from (Schell, 1992)

Strategy	Case study	Experiment	History	Survey	Archival analysis
Form of research question	How, why	How, why	How, why	Who what, where, how many, how much	Who what, where, how many, how much
Requires control over behavioural events?	No	Yes	No	No	No
Focuses on contemporary events?	Yes	Yes	No	Yes	Yes/No

## 5 FINDINGS AND DISCUSSION

Sections two, three and four have provided the theoretical background and literature review of performance management and measurement of enterprises, organizations, companies and SMEs, research methodology and strategies. In this section, the findings of the study are shown and the discussion of the entire paper.

First of all, the data sources of this study are from Enterprise and Industry, 2014 SBA Fact Sheet – Czech Republic (SBA Fact Sheet 2014) and the Final Report – July 2014 (Muller, et al. 2014). The annually published SBA Fact Sheets objective is to improve the understanding of up-to-date trends and national policies affecting SMEs. The Czech SMEs are important in the economy as in the European Union (EU). Table 5 below shows the basic figures of SMEs in the Czech Republic.

These figures are estimates for 2013 produced by DIW Econ, based on 2008 to 2011 figures from the Structural Business Statistics Database (SBSD – Eurostat). This data covers the ‘business economy’ comprises construction, industry, services and trade (NACE Rev. 2 section B to J, L, M and N), but not enterprises in fisheries, forestry and agriculture and the non-market service sectors for instance health and education. The drawback of employing Eurostat data is that for some countries the data may not be the same from those published by national authorities. The benefit is that the statistics are comparable and harmonized across countries. Figure 4 below shows the SMEs trends in the Czech Republic.

According to the (SBA Fact Sheet 2014), it is difficult to describe the trends in the demography of Czech SMEs because companies are documented separately from private entrepreneurs (self – employed) and the documenting methodology on the latter changed in 2013. Figure 5 below displays the Czech Republic’s SBA profile.

Tab. 5 – Czech Republic SMEs – basic figures. Source: Adapted from SBA Fact Sheet (2014)

			Micro	Small	Medium-sized	SMEs	Large
Number of enterprises	Czech Republic	Number	968,998	31,850	6,273	<b>1,007,121</b>	1,406
		Proportion	96.1%	3.2%	0.6%	<b>99.9%</b>	0.1%
	EU-28	Proportion	92.4%	6.4%	1.0%	<b>99.8%</b>	0.2%
Number of employees	Czech Republic	Number	1,132,769	637,865	654,056	<b>2,424,690</b>	1,100,327
		Proportion	32.1%	18.1%	18.6%	<b>68.8%</b>	1.2%
	EU-28	Proportion	29.1%	20.6%	17.2%	<b>66.9%</b>	33.1%
Value added	Czech Republic	Billion €	16	12	16	<b>45</b>	38
		Proportion	19.8%	14.5%	19.9%	<b>54.1%</b>	45.9%
	EU-28	Proportion	21.6%	18.2%	18.3%	<b>58.1%</b>	41.9%

Fig. 4 – The Czech Republic SMEs trends. Source: Adapted from SBA Fact Sheet (2014)

The figure of Czech SBA profile indicates that, the skills and innovation and the state aid and public procurement perform well. Though, the responsive administration (public administration) remains low: this hampers business opportunities and has negative spill – over effects in other areas. For instance, it is difficult for Czech SMEs to do business across borders, both outside the EU and in the single market, due to unfavourable export and import procedures. Other areas of SBA have average results. Thus, generally, the implementation of SBA has been modest. As a result, some improvements from previous measures introduced became manifest in the course of 2013. The field of second chance is an example, where data indicate that time needed to settle liquidation fell from three to two years. According to the SBA 2014 report, 5 of the 10 policy areas were addressed in 2013 during implemented policy measures. Hence, improving the application of the ‘think small first’ principle, skills and innovation and access to finance were the main focus. For example, skills and innovation contribute to the development of long – term competitive advantage. In addition, future improvements are expected from SMEs support strategy 2014 – 2020. Though, these strategies appear to provide attention to the skills and innovation, and access to finance. This might pose risks to other areas of SBA to keep up with developments in other EU countries. Figure 6 displays the number of adopted/ implemented policy measures in EU 28 per SBA principle – 2013/2014.

Fig. 5 – The Czech Republic's SBA profile. Source: Adapted from SBA Fact Sheet (2014)

Fig. 6 – Policy measures. Source: SME Performance Review 2013/2014 – Policy database

It is observed that, Access to finance saw the top policy progress (116) during this period, then Entrepreneurship (83) and Skills & Innovation (57), whereas Second chance and Single market with (8) and (15) measures, respectively. Generally, the number of SBA policy measures adopted/ implemented during this period 2013/2014 in EU 28 was higher than the previous period. Table 6 shows 2014 and 2015 forecast of annual growth in SMEs performance indicators – EU 28.

Tab. 6 – EU28 SMEs forecast. Source: Eurostat, National Statistical Offices and DIW Econ

Size class	Indicator	% change 2012 – 2013	% change 2013 – 2014	% change 2014 – 2015
Large	Enterprises	-0.40%	-0.49%	-0.25%
	Value Added	-0.03%	2.39%	2.90%
	Employment	0.05%	-0.08%	0.47%
SMEs	<b>Enterprises</b>	<b>0.90%</b>	<b>-0.23%</b>	<b>0.38%</b>
	<b>Value Added</b>	<b>1.12%</b>	<b>2.80%</b>	<b>3.44%</b>
	<b>Employment</b>	<b>-0.51%</b>	<b>0.16%</b>	<b>0.68%</b>

As illustrated in table 6, the value added in EU28 SMEs continues to increase; growing by 2.80% in 2014 and 3.4% in 2015. Employment by SMEs in the EU28 continues to increase by 2015 that is, expanding by 0.1% in 2014 and 0.7% in 2015. Therefore, according to the final report, these amounts to 740, 000 jobs in SMEs. EU28 SMEs is predicted to increase in 2015 by 0.38%. To sum up, in 2014 and 2015 outlook for SMEs in EU28 continues to expand by 6.3% in value added, 0.8% of employment and 0.1% for number of SMEs.

## 6 CONCLUSION

This research concentrated on the theoretical and empirical study of performance management and measurement of Czech SMEs with the aim to verify whether still SMEs in the Czech Republic performance is weak or not, and the current challenges and problems facing. Overall, this study has taken an overview of the theoretical background of performance management and measurement of organizations, showing the benefits and the need of a maturity model for enterprises, SMEs and companies. Followed by, an overview of literature review of earlier scholars' research of performance management and measurement focuses on SMEs, expanded enterprises, organizations and large companies. Then, an overview of research methodology and strategy, illustrating which scientific knowledge and approaches adopted. In addition, showing clearly the research method employed to conduct this study. The findings of this study confirm that, Czech SMEs plays an important role in the Czech Republic's economy as well as EU 28. However, comparing the SMEs in Czech with other EU 28 member states, Czech SMEs are growing (see table 5), as from the SBA Fact Sheet (2014). Therefore, Czech SMEs performance is improving for the better.

## Appendix

### Appendix A

Tab. 1 – The Characteristics of Maturity Levels. Source: Adapted from (Chelniciuc, 2010)

Level 1	The organization mission and objectives are not clearly defined. Processes are underdeveloped and not documented. Any success for the organization at this level is based on key individual competencies rather than organizational wide knowledge.
Level 2	Performance management practices are occurring within the strategic and operational level and less at the individual level. Activities and resources are identified to achieve goals. Operating unit's performance measures/metrics are identified. The organization does not have a purposed built IT system for data collection, nor the capability to disseminate the information across so the learning and improvement activities can occur.
Level 3	The efforts to disseminate performance management practices at the individual level are introduced, but there are gaps to be overcome. Measures tracking strategic and operational efficiencies are established to evaluate activities and work processes. Technology is used to support formal data integration and dynamic reporting. Enhanced data access and reporting.
Level 4	The organization can report the status of mission, goals, and efficiency of the activities. Data systems produce timely, relevant and accurate performance information. Performance management is a strategy and mission-driven throughout the enterprise. Performance ties resources to strategic plans' success and stakeholder satisfaction.
Level 5	The performance management system is integrated at all levels throughout the enterprise. Executive and enterprise-level accountability. Performance information helps pinpoint everyone's contribution to goal attainment. The organization provides clear transparency of cost and performance achievements to internal and external stakeholders.

## **SEGMENT OVER 55 YEARS OLD AS A NEW CHALLENGE FOR THE CZECH COMPANIES**

*Petra Barešová, Pavla Staňková*

### **Abstract**

The main aim of this study was to discover whether Czech companies providing leisure activities create specific marketing communication campaigns to target the segment of the population over age 55. Also to be ascertained was the level of interest of Czech companies in this societal segment and if they offer some of their products (services) to these customers. The second aim of this study was to identify what kinds of marketing communication tools they use. Results were found by analysing primary data obtained through an online research questionnaire distributed among Czech companies in 2014. The results show that Czech companies offer products (services) for this segment, but they do not design specific marketing communication campaigns to target this segment.

*Key words: aging, leisure industry, marketing communication, new trends*

JEL Classification: M31

## **1 THEORETICAL BACKGROUND**

Demographic changes and the rapidly increasing older population are currently important topics, as studies clearly indicate that the population is aging and will continue to do so in the coming years. (Malíková, 2011; EUROSTAT, 2011 Holmerová, 2006; Mumel, 2005; Leventhal, 1997) Statistics even show that 49 percent of the European population will be over age 50 by 2020. (Mumel, 2005) Similar figures are forecast for other countries, such as the United States, Australia, and Japan. (Long, 1998; Szmigin and Carrigan, 200) As a result, the older generations will likely dictate market trends and significantly affect the economy. (Dvorakova, 2011) For this reason, it is necessary to develop new marketing approaches and strategies. (Treguer 2002)

### **1.1 Aging and Old Age**

Each part of life is accompanied by specific changes that people can, in some cases, influence. On the other hand, it can also bring new possibilities and opportunities for everyone. (Malíková, 2011) Old age is generally perceived as problematic period of life associated with the health and social problems. In the 20th century, aging was for most of the people commonly associated with diseases, illnesses, social exclusion, dependency on others or on the health and social system. Several authors (Logan et al, 1992) (Dionigi, 2006) define old age as related to the health status or psychological changes. However, it is undeniable that old age brings about number of visible changes. Mühlpachr (2004) divided these changes into three groups - physiological, psychological and social.

The AXA (2008) research discusses the perception of old age by younger generation and whether they regard this part of life as pessimistic or optimistic. Czechs are, in comparison with other countries, more pessimistic nation when it comes to the retirement age. The countries which see this stage of life rather optimistically are namely: India, Malaysia, China or Thailand.

At the end of the 20th century, the tendency was to support and positively promote old age as a period of life when people can devote their time to activities they could not do in the productive life. The study "Berlin Aging" found out that elderly people (respondents were aged between 70 to 103 years) see themselves as fully active, being able to live an active life and, generally, their attitudes to the old age were positive. (Luo, 2009) Funderburk et al. (2006) and Harris & Dollinger (2001) suggested that the educational institutions should: strengthen and promote positive attitudes to older people and age; help to deal with this issue and positively spread the awareness of active aging among the general public. Malíková (2011) also showed the importance of seeing this part of life as an individual process and recommended not to consider this segment as homogenous group. The results of the research "50+ active" showed that the majority of Czechs over 50 years old are satisfied with their leisure time and activities.

## **1.2 Consumer Behaviour and Older Population**

It is obvious that current generation over 55 years old is significantly different from the previous generations. It is mainly because of the fact that current generation lives longer, healthier and more active life. These aspects lead to a different lifestyle, approach to life but also to shopping behaviour. (Mumel 2005)

Beck (1996) in his work highlights the demographic changes and new trends, leading to the creation of new markets and new opportunities in many sectors. Several authors (Long, 1998; Ahmad, 2002) hold the view that the target group over 55 years old can be interesting for the companies especially regarding their number, purchasing power or its diversity. With increasing age, the preferences and needs are changing, with that comes the need for different products, services in order to satisfy customers' expectations. The study of Herzmann and Petrova (2005) states that in the following twenty years, there will be three different groups of seniors in the Czech Republic - traditional seniors, modern seniors and wealthy seniors. Based on their study, modern seniors and wealthy seniors will be spending more money on travelling, entertainment, tourism, leisure activities and studying while wealthy seniors will spend more money on travelling, entertainment, spa, trendy cars and gastronomy.

According to the Czech Statistical Office (Czech Statistical Office, 2012), the current situation shows that Czech seniors spend most of their incomes on food and housing. They spend up to 5 percent of total expenditure on their households. (Kamenický, 2012) Statistics show that Czech people over 55 years old do not buy branded long term products in contrast to the rest of the population. Only 35 percent of people over 55 years old prefer branded goods, the rest consider the price the most important. On the other hand, people over 55 years old consume products, such as medicine, tea, vitamins or beer, in different amount than the rest of the population.

In the terms of hobbies and leisure activities, most people over 55 years old are interested in pets, gardening, reading books, walking, sports activities with their children and grandchildren. Based on the statistical analysis (Quis, 2012), men spend less than 10 percent of their income on recreation and cultural activities. These people also prefer to spend their holiday in the Czech Republic rather than abroad.

## **1.3 Integrated Marketing Communication**

As it was already mentioned in the previous chapter, the customer market over 55 years old is still growing and these customers will play an important role on the market. Therefore it is necessary to create effective marketing communication model and approaches to attract these customers.

The traditional marketing strategy discusses 4P model which includes product, place, price and promotion. In this case the emphasis is put on promotion however, the other three constituents of 4P are also important and have to be taken into consideration so that the customers' needs will be satisfied.

One part of the promotion is to create suitable marketing communication and select marketing communication tools. Nowadays lot of experts and companies tend to use holistic marketing concept, which highlight integrated marketing communication. Integrated Marketing Communication (IMC) is explained as a "concept, under which a company carefully integrates and coordinates their communication channels to the organization and its products has brought a clear, consistent and compelling message" (Kotler, 2007,) In other words, Lee & Park (2007) identify the IMC as a systematic combination (integration) of various communication tools and channels, but also as a joint coordination of all messages, so that it unifies communication mix of the company. Schultz (1999) sees the added value of integrated marketing communications in its entirety and its comprehensive plan combined with the individual marketing mix ensures clarity, consistency and coherence, but also brings a greater positive effect which has an impact on marketing communicative results of the company. Lee & Park (2007) point out that the integrated marketing communication and its implementation in the company's marketing strategy bring the significant benefits. On the other hand, Baack & Kenneth (2008) argue that the principles of integrated marketing communication and its complexity existed in the literature before without being termed and emphasized.

The process of integrated marketing communication and its implementation in the company can be considered from two viewpoints, tactical or strategic. The strategic approach, as stated by Porcu (2012), is explained by determining opportunities for planning marketing activities and development of businesses that will create long-term competitive advantages. The tactical approach is concerned with the short-term activities that will help to fulfil the strategic marketing objectives of the company. Kotler (2001) holds the view that the strength of integrated marketing is also based on the cooperation of particular company's departments while aiming at meeting the customers' needs (product management, sales, advertising, marketing research), but other departments also have to plan their concepts in order to meet the customer needs.

Porcu (2012) in his article presents four dimensions which strengthen the effect of integrated marketing communication. There are "one voice" (creating a single communication of the company), "cross-functional planning" (linking marketing communications planning between departments, not only in marketing), "interactivity" (mutual and long-term communication with customers but also with other stakeholders), "profitable long-term relations" (interactive communication leads to the creation of long-term relationships which is beneficial for the companies).

One of the objectives of integrated marketing communication is selection of marketing communication tools which fit perfectly to the strategy, but also ethically and effectively attract the customers.

Current customers can be divided into two groups in terms of attitudes to marketing communications. The first group are customers who are passive towards the promotion. In contrast, the second group contains customers, who are happy to be actively involved in the promotion process, for example through social networks, and who require marketing communications as a considerable interaction. Rakic & Rakic (2014) regard the growing implementation of digital media in the marketing communication as one of the current trends. The companies should follow these trends and adapt their marketing communications to them.

Fill (2009) in his book presents the basic tools of marketing communications including advertising, sales promotion, personal selling, public relations and direct marketing.

## **2 PROBLEM FORMULATION**

One of the survey's goals was to discover whether the Czech companies providing leisure activities are interested in the segment over 55 years old. There was a question if the companies create specific marketing communication strategy and what kind of marketing communication tools they use. Based on the available sources, it was founded that there are discussions about increasing number of older people, discussions about their significance in the future, but there is lack of surveys focused on marketing communication tools and suggestions which marketing communication tools should be used to attract this segment, especially on the Czech market.

## **3 RESEARCH METHODS AND METHODOLOGY**

The data presented in this paper were taken from the survey conducted in the Czech Republic in 2014. The research was designed based on the previous researches' experiences. The research design used in this work was deductive approach which allowed to set up the hypothesis and research questions based on the reading to gain a sense of key theoretical issues.

Quantitative primary data were obtained by questionnaire survey. This questionnaire was sent to the randomly selected companies which provide leisure activities in the Czech Republic, regardless of their business focus. The companies were selected via online databases which are available on the Internet. The online questionnaire was created in Formeese and was distributed by email. Open and closed questions with predefined answers were used in this questionnaire. There were in total 10 questions.

The research was obviously conducted under the ethical rules that all researches have to follow. In addition, respondents were also informed about the purpose of this research, the anonymity of their responses and were offered the opportunity to obtain the information about the results.

Before the survey started, there was a pilot research which was directed at 10 respondents to see whether all questions are understandable and clear, and whether the required data will be received from the questions. Based on their comments, two questions were modified.

As mentioned earlier, the deductive research approach was used in this research. Analysing the current sources and secondary data, two research questions and two hypothesis were introduced.

Research questions:

- 1) How many products Czech companies providing leisure activities offer to the target group over 55 years old?*
- 2) What kind of marketing communication tools companies use when trying to attract the target group over 55 years old?*

Hypothesis:

*H1: More than half of the Czech companies do not create specific marketing communication campaign to target group over 55 years old.*

*H2: There is no relation between the number of products intended for the target group and creation of the specific marketing communication campaign aiming at this group.*

The research questions were answered based on the statistical analyses of the primary data. The both hypothesis were tested based on the significant value  $\alpha=0,05$ . The  $\chi^2$  test was used for statistical evaluation of the H1 hypothesis to reject or not to reject the statement. The second hypothesis was evaluated by statistical analyses ANOVA test. This test was used to see if there is any relation between the two factors.

## 4 RESULTS

The total number of 287 respondents answered the questionnaire. The respondents were selected randomly within the companies which offer leisure activities throughout the Czech Republic. Representatives had three weeks to complete the online questionnaire. The respondent rate was 19.4% (i.e. 54 respondents).

The questionnaire consisted of various questions; some of them were used to indicate the features and characteristics of respondents (companies). The obtained data are shown in the table below (Tab. 1). The first part shows the division of the companies based on the number of employees. The most of the companies have 10 to 99 employees. The second question was related to their legal form, most companies are from non-profit sector (non profit organisations, citizens association or founded organisation). The respondents were also asked about the location of their customers. The majority of respondents answered that their customers are from the same district where the company is located.

Tab. 1 - Characteristic of the respondents. Source: own analysis

<b>Characteristic of the respondents</b>	<b>Relevant value</b>	
<b>Number of employees</b>	Entrepreneur without employees	5,6%
	1-9 employees	37,0%
	10-99 employees	42,6%
	100-499	14,8%
	More than 500 employees	5,6%
<b>Form of the company</b>	Non profit organisation	17%
	Citizens association	28%
	Entrepreneur	17%
	Founded organization	11%
	Ltd Company	28%
<b>Location of the company's customers</b>	Czech and foreigner customers	2%
	Location of whole Czech Republic	6%
	One Region	17%
	Town/city	30%
	District	37%
	More then one region	9%

The research question about interest and number of products of Czech companies in the target group over 55 years old was identified based on the two questions. The first question asked respondents about the number of their products which they are primarily offering to this generation. The second question answered the question of how many percent of the company's products portfolio are products for people over 55 years old.

The results show that 52% of respondents identified that the products targeting group over 55 years old create more than half of their products portfolio. These results can be compared with the number of products which companies offer to this segment. The numbers of products were divided into four categories: 1 – 3 products, 4 – 6 products, 7 – 9 products, 10 or more than 10 products. Most companies provide between 1 and 3 products or 4 and 6 products to the people over 55 years old. Almost 39% of respondents provides up to 3 products. In the second category (4 – 6 products) belongs 37% of the companies. The comparison of the number of products targeting people over 55 years old and their position in the company's product portfolio brings the following results. The obtained data showed that the first two categories (i.e. 1-3 and 4-6 products) mostly create less than half of the company's products portfolio. On the other hand, the rest of the two categories (7- 9 products, 10 or more than 10 products) create more than half of the company's products portfolio. Moreover, 26% of respondents stated that the products targeting people over 55 years old are the only products which company offers. From these results can be seen that the Czech companies providing leisure activities are aimed at this segment and even for some of them these, customers play the key role in the market.

The next section of the survey was concerned with the marketing communication tools which companies use to target their customers. The following graph illustrates which kind of marketing communication tools respondents used. More than half of the respondents have their own web page (almost 71%), they design leaflets or catalogues (68%), but surprisingly most of them use outdoor marketing communication tools including posters and billboards (87%). The grey line shows how many of respondents create the specific communication campaign targeting people over 55 years old by using particular marketing communication tool. As it can be seen from the graph (Fig. 1), only few companies design specific campaign and if so, they mostly use outdoor marketing communication tools, such as printed promotion materials including catalogue and leaflets, or online banner advertisement.

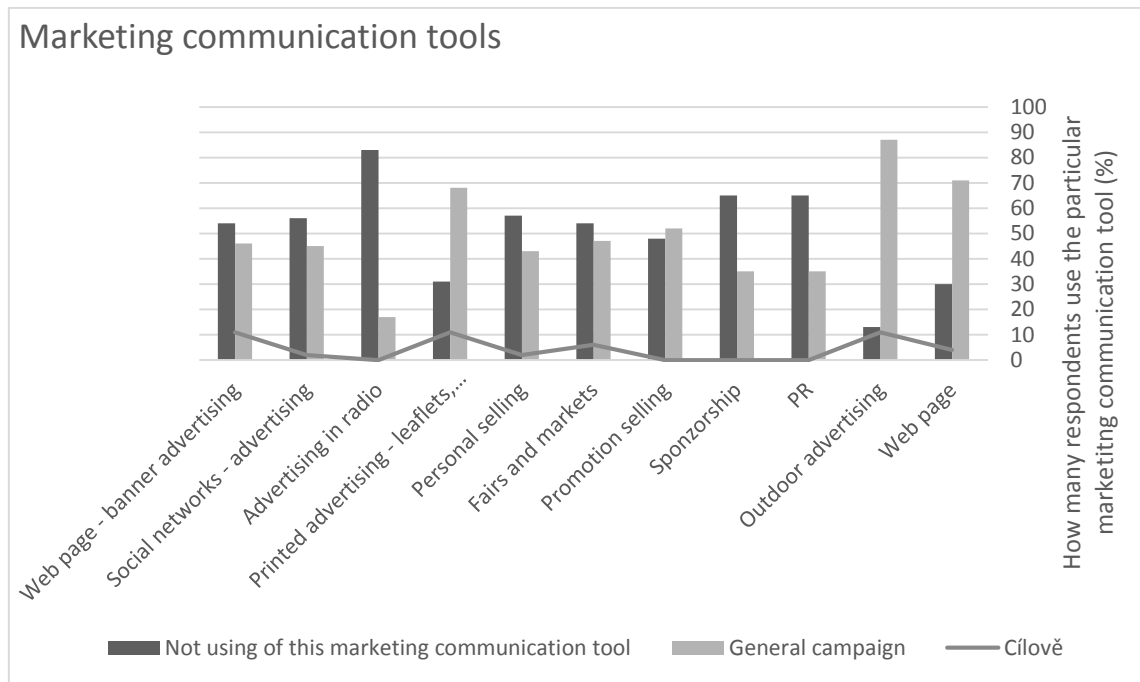

Fig. 1 - Marketing communication tools as used by Czech companies providing leisure activities. Source: own analysis.

## 5 CONCLUSION

The first hypothesis H1 was related to this topic. The hypothesis *H1: More than half of the Czech companies do not create specific marketing communication campaign to target group over 55 years old* was analysed by  $\chi^2$  test. The hypothesis was analysed based on the respondents' answers – Not using the marketing communication tools, generally using the marketing communication tool and using the marketing communication tool to specifically target people over 55 years old. Using of each marketing communication tool was compared with the required limitation of using (50%). The  $\chi^2$  test rejected the null hypothesis. In other words, the test rejected that more than half of the Czech companies do not use the particular marketing communication tools to create specific campaign and target customers over 55 years old.

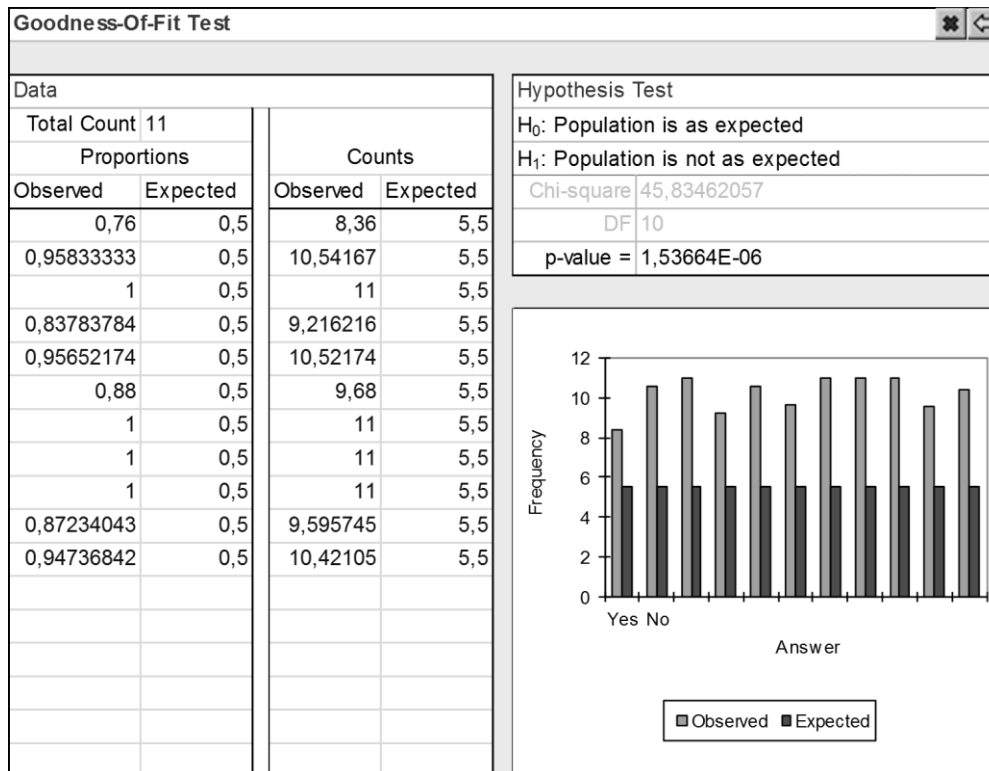

Fig. – Goodness-Of-Fit Test. Source: own analysis.

In the next part of the survey, respondents were asked about creation of the general specific marketing communication campaign. The given questions obtained data used to analyse the hypothesis which were created for this research. As it can be seen from the table 2 below, only 37% of respondents do not create specific marketing communication campaign targeting people over 55 years old. Almost 13% of these respondents provide up to 3 products for this segment, 9% of them offer from 4 to 6 products, more than 7% deliver between 7 and 9 products and the same number of percent provide 10 or more products. The rest of respondents (almost 63%) do not create specific campaign even though their products are available for people over 55 years old.

Tab. 1 - Number of products and marketing campaigns. Source: own analysis.

Campaign	Number of products				Total number
	1-3 products	4-6 products	7-9 products	10 or more than 10 products	
Company created specific campaign	12,96%	9,26%	7,41%	7,41%	37,04%
Company does not create specific campaign	25,93%	27,78%	1,85%	7,41%	62,96%
<b>Total number</b>	<b>38,89%</b>	<b>37,04%</b>	<b>9,26%</b>	<b>14,81%</b>	<b>100,00%</b>

The second hypothesis (H2: There is no relation between the number of products intended for the target group and creation of the specific marketing communication campaign aiming at this group.) determined whether there is relation between the two factors – number of products and creation of the specific campaign targeting people over 55 years old. To analyse this hypothesis, ANOVA test was used. The results showed that the relation between these factors is insignificant. Therefore the second hypothesis was not rejected (p-value 0,4 > 0,05).

There were several questions to find out why companies do not create the specific campaign. At first, it might have been due to the fact that the companies do not consider the specific campaign beneficial or they do not have enough experiences and knowledge to create the campaign. Another possible explanation might be that the demand is higher than supply, so companies do not need to focus their resources on creating specific campaign for this segment. These questions could be the objective for further studies.

## **IMPACT OF ALLOWED DEBT RELIEF OF INDIVIDUALS IN 2009 - 2014 ON CURRENT SATISFACTION OF CREDITORS**

*Dagmar Bařinová, Vojtěch Pinter, Kateřina Branžovská*

### **Abstract**

This article deals with personal bankruptcy and with impact of debt relief in the form of rescheduling on creditors. As part of the research the statistical sample of 366 borrowers in debt relief with the repayment schedule since 2009 was studied. Evaluation covered the whole process of debt relief within 5 years until the end of paying the rescheduling. Effect on debtors, creditors and also on future development in debt relief in the Czech Republic was evaluated. The research compared the total amount of debts due to borrowers, their final amount paid as well as level of satisfaction of creditors, further the number of months needed to repay the debt and also monthly installments for creditors. In the research there was examined the composition of filed claims and the representation of individual creditors in personal bankruptcy. In view of divide the individual creditors according to sectors the most dominate was banking sector which formed most of the identified claims. Furthermore, it was found that most borrowers repay more than half of their obligations and in addition they try to pay the statutory minimum off as quickly as possible.

*Keywords: debt relief, personal bankruptcy, insolvency, banking and non-banking sector, credit registers.*

JEL Classification: D1, G2

### **1 INTRODUCTION**

Basic information about the debt relief are defined by Actno.182/2006Coll., about bankruptcy and its solution. This legal standard is divided into three titles - general provisions, methods of solving the bankruptcy and common provisions.

Pilátová (2011) defines the basic relationship between the creditor and the debtor at the base of the contractual relation. In this relation the creditor is entitled to performance and the debtor has an obligation to perform. The basic assumption for at least partial satisfaction for the creditor is either actual filing of an insolvency proposal for the debtor or at least timely application into proceedings already commenced. (Crhová & Kuderová, 2013)

In solvency can be solved by bankruptcy, reorganization or debt relief. All creditors may be satisfied from the yield of realization of estate and their satisfaction is due to their ratio on debt. Debts of unsatisfied creditors do not expire and they are thus entitled to their further enforcement. Reorganization is mainly used by the debtor entrepreneur who performs recovery while maintaining the company's operations. The purpose of debt relief is simply an exemption the debtor from his debts, either in the form of five-year repayment schedule with at least 30% of fulfillment or one-time realization of assets.

The main benefit of debt relief by Hanousková (2010) is remission of remaining debt if the debtor complies with all the obligations according to the Insolvency Act. Another advantage is stopping all enforcement proceedings and growth of all charges and penalty fees for not paying the loans. Among the disadvantages Hanousková (2010) states the requirement for deposit payment before the initiation of insolvency proceedings up to 50,000 CZK.

Furthermore, the borrower cannot invoke against the decision of the court. If the court does not approve the debt relief, the debtor's situation is resolved with the slight bankruptcy – accelerated insolvency proceedings instead of common bankruptcy. Paseková and Bařinová (2013) further claim that approved debt relief deeply affects every debtor especially in the social area throughout the duration of the debt remittance according to a payment schedule.

Maršiková (2009) describes two ways for logging claims in the insolvency proceedings – for creditors and debtors. Creditor has to log himself in the insolvency petition along with his claims. On the contrary, if the debtor submits his insolvency petition, all creditors are entitled to submit an application for insolvency proceedings after the commencement of the insolvency court (30 day limitation period).

The way of filling claims in the insolvency proceedings is published. All creditors can find it out in the call for applications which is made by the insolvency court after commencement of insolvency proceedings. This claims must contain the general requirements and the reason of the formation. If the claim is secured the creditor must indicate the type and duration of collateral. All enforceable creditors are obliged to state the facts on which is the enforceability based. Maršiková (2009) states other creditor's right to change the amount, reason or the order of filed claims.

After the deadline for registration of claims the review meeting will be held within 30 days after the deadline. Kozak (2008) describes the review proceeding as a meeting for examination of all claims filed according to the list. This meeting is compulsory only for the insolvency administrator. During the review meeting, the insolvency administrator, debtor or logged creditor may deny the authenticity, amount and order of all claims filed. The result of the review hearing is a list of filed claims which will be paid during the debt relief.

Act No.21/1992Coll., about banks, describes the conditions of establishment the banks. This Act also divides the creditors on the banking and non-banking sector as the most common types of creditors in debt relief. Loans from banks are safer type of loans and they have also lower interest rates than non-banking institutions. However the loan approval by banking institutions is time-consuming and the loan may not always be granted. Among the largest banking institutions in the Czech market belongs for example Česká spořitelna a.s., Komerční banka a.s., ČSOB a.s. and UniCredit bank a.s.

The value of the performance of rescheduling is currently around 50% at its end. The main reason is establishment of minimum threshold performance (30 %) and also poor economic situation of borrowers (unemployment, low income). According to Kinslingerová (2013) the other aspect of low satisfaction of claims is the fact that no one explores the reason why debtors became insolvent and end in subsequent debt relief. Due to the growing number of personal bankruptcies and complexity of its approval, bankruptcy courts are not able to examine this aspect. Furthermore, according to Kinslingerová (2013) the courts should reconsider the possibility of repeated debt relief since the current legal legislation does not regulate their number. Therefore the "notorious" borrowers can go through the process of deleveraging repeatedly.

Credit registers are the most commonly used in assessing the creditworthiness of the clients. Kalabis(2012) defines the registry as a database of all types of clients - individuals, legal persons or entrepreneurs who are associated with certain lending operations. Purpose of this registry is providing client's data which helps the banking institutions to prevent providing a loan to non-creditworthy clients. Among the most popular registers belong Centrální registr úvěřů (operated by ČNB), CCB (Czech Credit Bureau) and Solus.

Smrčka (2007) discusses a similar theme which examines the social and psychological effects on the person of the debtor. According to him the main problem of debt is at the very beginning when the "potential" debtor does not realize the real necessity of the first loan. This carelessness can cause a ripple effect (reduction of attention to the risk of over-indebtedness) which ends with the bankruptcy of debtor. On the contrary, bank procedure is exactly the opposite- applicants for the first loan are almost never rejected. Conversely, the deterioration of the financial condition of the borrower increases bank's alertness. Borrower cannot obtain additional funding through this way anymore. Then the debtor's path leads towards the non-banking companies with very tough conditions. The borrower ends in debt spiral.

Paseková and Bařinová (2013) came with similar conclusion. The conditions for borrowing financial resources from financial institutions that not fall under the supervision of the Czech National Bank are markedly unfavourable. Interest and fees for providing loans are frequently many times higher than borrowed amount.

Crhová and Kuderová (2013) state that insolvency proceeding is becoming highly current theme in view of the adverse economic situation in the Czech Republic which has resulted in dramatically rising number of proposals filed at the insolvency courts.

## **2 ANALYSIS OF PERSONAL BANKRUPTCY**

The main objective of this research was evaluation of persons (resp. borrowers) who are in debt relief through rescheduling since the end of 2008 and especially since 2009. Debt relief lasts for 5 years. It means that debt relief which was approved in 2009 can be evaluated after those 5 years (in 2014). Our research was based on these data. We made an overall assessment of these borrowers with an indication of trends in future development in coming years. The second objective was to evaluate the composition of creditors whose claims appears in debt relief most frequently. This sample is abstracted of borrowers who are in debt relief in the form of realization of assets (in practice, this way solves only about 2 % of debt relief).

The overall statistical sample that we studied in the survey reached a specific value of 366 borrowers. For these borrowers we made an analysis of individual and total repayments in the context of debt relief and also the analysis of proportional representation of individual creditors for each debtor. Since the performance of rescheduling is designed for predetermined period of time which is 5 years (60 months), this research is based on borrowers who were allowed to debt relief at the end of 2008 and during 2009 (whose debt relief ended in 2013 or 2014). Evaluation of debt relief for this sample was processed in the second half of the year 2014. The average number of installments for all borrowers reached 56.19 months which is less than specified 60 months. This situation is caused by the fact that some borrowers fulfill its payment schedule to more than 100% of the expected level of performance at the end of the repayment schedule. Basically, this means that the borrower will pay its obligations before the predetermined period for performance of payment schedules that is before the expiry of 60 months.

The overall survey was quite extensive and also difficult for data processing. Therefore we used help of fifth grade students of the Faculty of Economics VŠB - TUO who performed basic analysis of individual borrowers. All available data were used from publicly accessible locations (primarily from the website of the insolvency register - [www.justice.cz](http://www.justice.cz)) and therefore there was no privacy violation. Fundamental evaluation is based on the overall summarization and total averages of individual borrowers.

### 3 RESEARCH RESULTS

Regarding other characteristics of statistical sample of borrowers it can be noted that this sample was represented by 59.3 % with men (which is 217 debtors) and 40.7 % with women (149 debtors). The average age of both genders was 48.8 years (in 2014) when the youngest was 27-year-old woman and the oldest 77-year-old man. Two borrowers of this sample died during debt relief (the first was man after 58 months of performance and the second was woman in the 45th month of performance rescheduling). They both reached the minimum performance of rescheduling - concretely 79% and 34% and they both are represented in some parts of the research.

The value of all filed claims of the sample is CZK 214 million. In review meetings which follow after the expiration of final deadline for filing the claims (after 30 days) the observed value was slightly lower, almost CZK 210 million (calculations in the research are based on this value, not on amount of filed claims). The resulting difference is caused by the situation where some claims submitted at the review hearing were negated by creditors or by insolvency administrators regarding their value, order or authenticity.

Fig. 1: Individual representation of the most numerous creditor entities and their share in the total value of filed claims. Source: own research

In terms of the representation of individual creditors in the statistical sample the total number of creditors was 102. A total of 2,505 claims was submitted in the insolvency proceedings. It therefore follows that one borrower has 7 different lenders. This value could be realistically slightly higher because the research has been abstracted from those borrowers who had more than 8 filed claims respectively creditors. Nevertheless, some students did research including those borrowers who partially crossed this threshold. It was about 90 borrowers who had primarily 9 or 10 creditors. One borrower had even 18 creditor entities.

The figure 1 illustrates some important information regarding individual creditors who enrolled their claims in insolvency proceedings. After approval of debt relief through

rescheduling are these lenders relatively satisfied from regular or irregular installments. The figure shows the most common creditor entities and their total filed claims (both absolute and percentage terms). The figure specifies those creditors whose total amount of filed claims exceeded the value of CZK 1 million. The last column includes all those creditors whose total amount does not exceed this limit. This group includes 76 creditor entities (from a total of 102 there was only 26 subjects over one million that are shown in the chart namely). Ensure creditors are not included in this group since they form only 1.5% of the total amount of established entitlements. They are satisfied beyond repayment schedule individually by the collateral. It is obvious that after summarizing of all creditor entities the final amount (that was found in the review meetings) is CZK 210 million.

In the research, we also further studied the total amount of debts of each borrower. It can be seen in figure 2 how many borrowers have occurred in each of these intervals. The most common amount of debts owed in debt relief is a value in the range of CZK 300,000 to CZK 400,000 which represents about 17 % of all borrowers in debt relief (the same value of 17 % of borrowers is represented by debtors who owe more than CZK 800,000, thus in the interval between CZK 800,000 and 2,200,000). The majority of borrowers is in the group of 100,000 - 800,000 CZK (marked in red with an average 41 borrowers per interval) followed a group of 800,000 – 1,500,000 CZK (marked in yellow with average 9 borrowers per interval) and the smallest group consists of borrowers with outstanding amount over 1.5 million CZK (marked in blue with an average 2 borrowers in interval). Within the statistical survey no one reached higher amount than 2,200,000 CZK (specific maximum amount was 2,193,608 CZK).

Fig. 2: The number of individual borrowers according to their total debts in debt relief.  
Source: own research

The research also observed the average borrower in debt relief and his composition of creditors. According to the facts above the average borrower has an obligation in debt relief 573,769 CZK (which is total debts of CZK 210 millions divided by the total number of borrowers in statistical sample - 366). Furthermore, we found out that the average level of satisfaction of creditors at the end of debt relief is about 55.6 % so the average borrower pays

only CZK 319,015 (55.6% of the amount of CZK 573,769). Since the debtor fulfilled the statutory minimum threshold performance of 30% the rest of owed amount is forgiven by the court in the context of debt relief at the end of rescheduling. The average borrower has monthly payments to creditors CZK 5,677 (CZK 319,015 divided by average number of months in debt relief - 56.19; calculation are without the influence of extra installments or changes in performance in different months) and monthly remuneration of the insolvency administrator in the amount of 1,089 CZK (legal basis 900 + 21% value added tax if the insolvency administrator is taxpayer).

The average borrower is shown in figure 3 (which already partially modifies figure 1). As we can see, the composition of creditors is the same as in figure 1. The only change is in recalculation of value per borrower reduced to the value of the average fulfillment, thus 55.6 % (which represent the blue columns while the red represents the fulfillment of 100 %). The value of all red columns is abovementioned amount 573,769 CZK, but since the average borrower has lower performance indicated by blue column the total amount is only CZK 319,015.

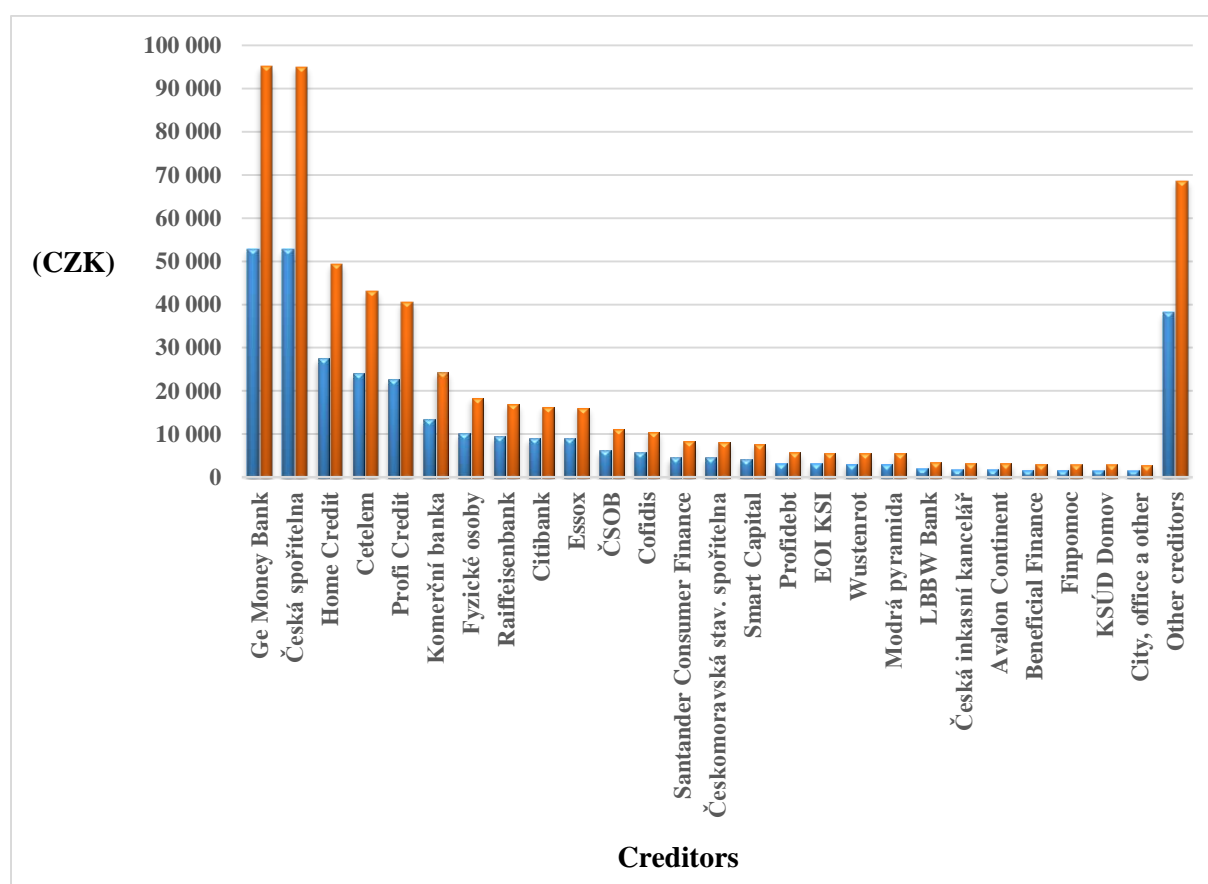

Fig. 3: The most common creditors of the average borrower with average fulfillment 55.6%.  
Source: own research

In terms of composition of creditors on banking, non-banking and public sector we can see that dominant institutions belong to the banking sector. It is mostly represented by GE Money Bank, Česká spořitelna and Komerční banka. Dominant institutions from non-banking sector are Home Credit, Cetelem and Profi Credit. Most creditors from public sector is among individuals (primarily members from the family, as well as judges, bailiffs), public institutions

(liabilities to municipalities - fees for waste, financial and customs authorities) and the owed amounts for gas or electricity (it is not shown in the figure because the total amount did not reach CZK 1 million).

## 4 CONCLUSION

Personal bankruptcy or solution of debtor's bankruptcy in the form of debt relief is the most common way how can an ordinary person get rid of his debts and start a new life "from scratch". This process has become increasingly popular. Number of those who use debt relief grows every year. As the debt relief can be used already since 2008 (so most of the first debtors ended their repayment schedules after 5 years in 2013) it is possible to infer some conclusions about the application of this "process" in practice.

In his research of statistical sample we concluded that the majority of borrowers fulfills their obligations roughly over half of their total debt. They are also trying to meet the statutory minimum as quickly as possible in order to be exempted from the remaining debt at the end of the performance rescheduling. From the perspective of lenders the most common are stakeholders from the banking sector that forms most of the identified claims.

It will be interesting to follow this development further and watch borrowers who entered into debt relief in 2010 and 2011 so they end their five-year performance of rescheduling now or in the near future.

## **SELECTED ASPECTS OF QUALITY OF BUSINESS ENVIRONMENT IN SEGMENT SME. A CASE STUDY FROM SLOVAKIA.**

*Jaroslav Belás, Yuriy Bilan, Petr Novák, Juraj Sipko*

### **Abstract**

SMEs play an important role in the economic system of Slovakia. In this context it is considered to be important to examine the factors that create the quality of the business environment. The aim of this article is to define, quantify and compare the significant attributes of quality of the business environment for small and medium-sized enterprises (SMEs) in selected regions of Slovakia. Within this stated objective, relevant factors and business relationships between entrepreneurs and the socio-economic system were analysed. The entrepreneurs' perception of their environment (motivation to start a business, the most important characteristics of entrepreneur, society, state, universities, etc.) was evaluated. The data was collected through a questionnaire. We compared important factors of business environment in the most economically developed region of the Slovak capital to the average regions of Trenčín and Zilina. On the basis of the results of our research, we can conclude that the most important motive for starting a business in all these regions of Slovakia was money. It was found that there were no differences between the individual regions. In the entrepreneurs' point of view, the most important characteristic of an entrepreneur is not being afraid to take risks. Other frequently chosen qualities were expertise, responsibility and persistence. We found no statistically significant differences in the perception of the importance of not being afraid to take risks among the selected regions. Only 6.70% of entrepreneurs in the Zilina region think that society perceives them positively. The numbers in the other regions were even lower. Since more than 60% of entrepreneurs in all the selected regions stated that the State should support them financially. Our research confirmed that entrepreneurs evaluate the level of higher education rather primly.

*Keywords: Small and Medium-Sized Enterprises, regional differences, motives for entrepreneurship, characteristics of entrepreneurs, government business support, the use of theoretical knowledge*

JEL Classification: L26, R11

## **1 INTRODUCTION**

SMEs play an important role in the economic system of Slovakia as well. In this country, the share of SMEs in the total number of active enterprises was 99.2%; in the total employment it was 59.5%. The share of added value was 55.6% and the share of SMEs in the profit before taxes was 51.6% in 2012. (Národná agentúra pre rozvoj malého a stredného podnikania, 2013)

Despite the fact that 99.2% of enterprises from total number of active ones in Slovakia are represented by SMEs, there is no clear understanding of the aspects of quality of business environment in their segment. And it is not just the case of Slovakia, there is a similar situation in each country of the world, but still there are some common features for SMEs mentioned in the literature.

One of the basic common features of SMEs which is a prerequisite to almost all other features is the smallness of the enterprises, resulting in low complexity of their structure. Therefore, management structure is plain and simple, allowing the managers to easily control all

operations of the enterprise, which in its turn results in flexibility of SMEs and creates coordination advantages. SMEs management has a personalized nature, since they are influenced by the owners (natural-persons entrepreneurs) to a large extent. Simple structure of SMEs is their advantage, because almost all organization may be controlled by a single persons simplifying, for instance, planning and decision-making processes. They do not mean that there are no formal procedures or planning itself, they mean that they are used more implicitly, leading to higher effectiveness compared to larger companies.

For the successful development of a company it is necessary to create favourable conditions for the growth of business awareness and shape a good quality of business environment and effective relationships between firms and their environment, i.e. society, the state, politicians, banks, etc.

In this article, significant attributes of the creation and development of the business environment of the SME segment in the selected regions of Slovak Republic were examined.

## **2 PROBLEM FORMULATION**

Current research papers intensively deal with entrepreneurship and business environment from many points of view, such as economic, institutional or cultural context, influence of gender and age on entrepreneurship, business orientation, customer orientation, financial risks, etc. We can also mention researches (Bernat et al. 2012) provided us with interesting insights into the entrepreneurship traits of the young generation of entrepreneurs.

According to Cumming, Johan, and Zhang (2014), entrepreneurship has a significantly positive impact on the GDP/capita, exports/GDP and the number of patents per population, and a negative impact on unemployment rates. Their findings point to institutional and cultural impediments to the effectiveness of entrepreneurship. Institutional/legal barriers are likely to have a negative impact on entrepreneurship. These barriers influence the decision to become an entrepreneur.

In recent times, we are facing more complex and global challenges. Enterprises, especially SMEs, have to work hard in order to keep the competitiveness and to sustainably develop, as outlined by Bernat and Bartkowiak (2012).

Entrepreneurial orientation represents a key element for the success of SME (Brockman, Jones, Becherer, 2012, Boso, Story, Cadogan, 2013). Soininen, Martikainen, Puumalainen, Kyläheiko (2012) consider the following characteristics of entrepreneurial orientation to be an essential for making business: innovation, risk acceptance and proactive approach. Lumpkin and Dess (1996) added the other features to the abobe characteristics: aggressive approach to competition and autonomy of the entrepreneur.

Entrepreneurial orientation is also in question nowadays as it is considered to be an essential driver of the high financial performance of companies. For instance, Alegre and Chiva (2013) discovered a positive relation between entrepreneurial orientation and innovation levels. Besides, a positive relation between innovation levels and a company performance was found. The direct influence of entrepreneurial orientation on a company performance is low and not significant. Similarly, Soininen, Martikainen, Puumalainen and Kyläheiko (2012) consider innovativeness, risk-taking and proactivity as essential characteristics of entrepreneurial orientation. The results of their studies do not support the assumption that entrepreneurial orientation is positively related to the profitability of small firms. On the other hand, there is a positive relationship between the entrepreneurial orientation of a firm and a firm's pace of growth. According to Eggers, Kraus, Hughes, Laraway and Snyckerski (2013), to drive itself to grow, a firm needs to deploy a strategy centered on entrepreneurial orientation or else risk

stagnation occurs. In this regard, Lasagni (2012) indicates that innovation performance is higher in the SMEs that are proactive in strengthening their relationships with innovative suppliers, users and customers. Boso, Story and Cadogan (2013) argue that a high degree of entrepreneurial orientation maximalises company performance when operating in less developed countries.

Furthermore, customer orientation is considered to be an essential element for small firm success. (Brockman, Jones and Becherer, 2012). Their results support the overall positive influence of customer orientation on performance and indicate that the influence is stronger as risk-taking, innovativeness and opportunity focus increase.

Nonetheless, there are only a few studies dealing with regional aspects. One of them is a study by Stuetzer, Obschonka, Brixy, Sternberg and Cantner (2014) that examines connections between regional characteristics and individual entrepreneurship. They found no empirical evidence for a direct effect of the regional characteristics on an individual's start-up intentions and engagement in the start-up activity. Their findings point to relevance of the indirect effects of the regional characteristics on individual entrepreneurship. Individual opportunity perception might play an important role in the cascading-down process of regional characteristics towards the individual. However, even inhabitants of one region can differ in their perceptions of business opportunities. This could be caused by several personal and social influences. Secondly, Simon-Moya, Revuelto-Taboada, Guerrero, Hack and Cantner (2014) point out there are significant differences among business environments of various countries and even regions. The authors suggest that politicians in every single country have to adjust the trade laws to conditions of the respective country. The same laws in countries or regions with different economies can lead to totally different results.

Business activities are significantly determined by the environment of a company, which forces it to use a particular method of behaviour, to use the choice of particular business goals and ways of achieving them. In this context, a crucial role is played by social environment and political and legal environment that is created by state authorities. Governing bodies on all levels attempt to foster entrepreneurship by setting up different strategies (Greibeníček et al., 2013), national governments often act with the help of larger schemes such as cohesion policy which are also heavily focused on entrepreneurial environment (Hájek et al., 2014).

According to Hájek, Grebeníček, Novosák (2011) the concept of innovation has become a development mantra in the fierce global competition. Competition is not limited to firms; it is also relevant for territories. An observed trend which is not surprising is the number of support tools that have been developed to reinforce the position of territories and their actors in the innovation processes. Clusters and regional innovation systems are the most important of them.

As far as we know, there exist no papers examining regional aspects of the business environment creation in Slovakia. Exactly this is the reason why we decided to carry out our research.

The aim of this article was to define, quantify and compare the significant attributes of quality of the business environment for SMEs in the selected regions of Slovakia. Within this objective, relevant factors and business relationships between entrepreneurs and socio-economic system were analysed.

In our research we compared important factors of business environment in the most economically developed region of the Slovak capital to the average regions of Trencin and Zilina. Our aim was to measure the regional differences of business environment in Slovakia.

### **3 METHODOLOGY AND DATA**

The research on business environment was conducted in 2013 in the selected regions of Slovakia through a questionnaire survey. In the Bratislava region (BA), 102 SMEs have been reached; in the Zilina region (ZA), 164 SMEs have been reached and in the Trencin region (TN), 105 SMEs have been reached. Companies' data was provided by their owners.

The composition of these regions has been chosen because it enables us to compare business environment in the most economically developed region to the averagely developed regions. Our aim was to measure the differences among these regions and to define their significance.

The Bratislava region is the region with the best economic performance and creates 26% of the total Slovak GDP. It has an area of 2,053 km<sup>2</sup> which means it is the smallest region of Slovakia. The number of inhabitants was 628,686 and the unemployment rate was 5.4 % in 2011. According to the data of Eurostat, the Bratislava region was the fifth richest region in the EU concerning GDP per capita in 2011. With 1.86 times the EU average, it overtook such regions as Stockholm, Prague or Vienna. The economy of the Bratislava region contains all the economic sectors based on the traditional industrial production of goods. The most important industrial sectors are the chemical, automotive, electronic and food industry and mechanical engineering. Over the last few years, the Bratislava region has become a European centre of automotive industry representing 30% of the overall Slovak export. (Bratislavský samosprávny kraj, 2014)

The Trencin region has an area of 4,502 km<sup>2</sup>, has about 600,000 inhabitants, GDP per capita reached 10,744 EUR in 2010 and the registered unemployment rate was at 10.89% in 2012 (significantly below the overall Slovak average of 14.44%).

The Zilina region has an area of 6,800 km<sup>2</sup>, total population is up to 700,000 and the population density is 102 inhabitants per km<sup>2</sup>. The unemployment rate was raised to 11.91% in 2011. The GDP per capita was 10,794 EUR in 2011.

In our research in the Bratislava region, the largest share of surveyed companies was comprised of SMEs operating in trade activities (33%), followed by construction firms (12%), manufacturing companies (7%), transport companies (1%) and agricultural enterprises (1%). The remaining share was formed by companies operating in other sectors.

In the Trencin region, the structure of companies was as follows: manufacturing companies (21%), trade companies (21%), construction companies (18%), transport companies (4%) and agricultural firms (5%). The largest portion of companies operated in other sectors (31%).

In the Zilina region, the structure of companies was as follows: 17% of companies operated in the manufacturing sector, 21% in the trade sector, 17% in the construction sector, 6% in the transport sector and 1% in the agricultural sector. The largest portion of companies operated in other sectors (38%).

From the total number of 102 surveyed firms in the Bratislava region, 54% of them were doing business for more than 10 years, 19% of them between 5 and 10 years, 27% of them between 1 and 5 years. Therefore, it can be stated that the research was examining quite experienced entrepreneurs from this region. The size structure of companies was as follow: 83% were micro-enterprises, 12% were small enterprises and 5% were medium-sized companies.

From the total number of 105 surveyed companies in the Trencin region, 54% of companies do their business more than 10 years, 25% do their business from 5 to 10 years and 21% do their business from 1 to 5 years. The size structure of the companies was as follows: 62% were micro-enterprises, 31% were small enterprises and 7% were medium-sized enterprises.

In the Zilina region, of 164 surveyed companies 38% do business more than 10 years, 32% represents firms which do their businesses from 5 to 10 years and 30% of surveyed companies do businesses from 1 to 5 years. Thus companies surveyed in this region were equally distributed from the perspective of business duration. As for the size structure, 66% was represented by micro enterprises, 20% were small companies and 14% were medium-sized enterprises.

It can be assumed that there are numbers of motives for starting a business. The main reasons for starting a business in Slovakia are: the need for self-fulfillment, autonomy and independence, achieving higher income, time flexibility and the need to bring something new (Podnikajte.sk, 2010). Within the survey of Iuventa (2012), in which respondents could choose more than one answer, 59% of young entrepreneurs stated they wanted to be independent in their economic decisions, 55% wanted to realise their dreams or business ideas, 27% declared their employment did not satisfy them, 27% started a business because of money, 20% were not satisfied with their working hours as employees, 19% declared they did not have any other option and 6% of respondents took over a family business.

Therefore, we hypothesize the following:

H1: The most important motive for starting a business is money.

H1a: There are significant differences in the perception of the most important motive to start a business among the selected regions of Slovakia. We assume entrepreneurs in the Bratislava region stated more often than entrepreneurs in the Trencin and Zilina regions that the most important motive to start their business was that they perceived it as a mission.

The business environment is also determined by personal characteristics of individual entrepreneurs. Creativity, risk taking and independence increase the probability of becoming an entrepreneur and decrease the probability of becoming an employee (Knórr, Alvarez, and Urbano, 2013). Almeida, Ahmetoglu and Chamorro-Premuzic (2014) show that META model (Awareness, Vision, Creativity and Opportunism) is the strongest and most consistent predictor of entrepreneurial activity. Entrepreneurial individuals are characterised primarily as enterprising and creative, and to some degree as social and investigative.

As entrepreneurs have to perform various tasks, they do not need only knowledge, competence and expertise, but also a complex of skills and abilities influenced by their personality. These are for example risk tolerance, emotional stability or an internal control helping them to trust their decisions (Caliendo, Fossen and Kritikos, 2014). In this context, Ilouga, Mouloungni and Sahut (2014) point out that the commitment to the profession of an entrepreneur is considered as long, complicated, loaded with obstacles, difficult to achieve, and requires the vocational skills that will enable the person to protect his or her goal from distractions, to persevere and to optimise the plausibility of achieving it. Entrepreneurs must demonstrate some resistance against the uncertainty concerning the future through their self-motivation, self-determination and initiative so as to overcome their fears and worries.

According to Deáková, Drážovská, Grznárik and Kondášová (2010), the most important personal qualities for an entrepreneur are: courage, self-reliance, responsibility, determination, perseverance, proactiveness, creativity and scholarship in the particular area in which this businessman intends to do business.

Kvietok (2013) adds that a decision to take on business risks is symptomatic for a certain type of people, in more detail for individuals who are more risk tolerant are more likely to start up firms (Hvide, and Panos, 2014).

In line with the findings of previous research, we hypothesize the following:

H2: The most important feature of an entrepreneur is not being afraid of taking risks.

H2a: The differences in the perception of the above mentioned key characteristics of an entrepreneur are not significant within the selected regions.

Various surveys show that the perception of entrepreneurship by society is still relatively negative in Slovakia. For instance, according to the survey of National Agency for Development of Small and Medium Enterprises, 69.9% of respondents think entrepreneurs in Slovakia try to quickly achieve as high profits as possible and 78.2% believe entrepreneurs are getting rich by taking advantage of ordinary people and are abusing their employees (Národná agentúra pre rozvoj malého a stredného podnikania, 2010).

As a result, we hypothesize the following:

H3: Less than 20% of entrepreneurs think society perceives them positively.

H3a: There are no significant variations in the opinions of entrepreneurs regarding this issue among the selected regions.

Generally, Slovak entrepreneurs evaluate the approach of the State to their needs and interests negatively. For instance, the Business Environment Index in relation to Slovakia, which is prepared by the Business Alliance of Slovakia, fell in 2011 to the historically lowest level since 2001 (Podnikateľská aliancia Slovenska, 2012).

In this context, it was interesting how entrepreneurs assess the state financial support of business and the following hypotheses have been set:

Therefore, we hypothesize the following:

H4: More than 60% of entrepreneurs think it is right that the State supports them financially.

H4a: There are no regional differences in the assessment of the State's financial support.

At present, more and more words of criticism of the educational system in Slovakia are being published even though there are no relevant objective findings and information concerning this issue. For example, Czech entrepreneurs have a highly critical attitude towards their school system. The vast majority (79%) of them believe that the Czech educational system is not adapted to the needs of the economy and business (Společnost g82, 2013). Such critical convictions are spread in Slovakia as well. There is a surplus of college students and a deficit of expert professionals (who would perform manual work for instance).

Therefore, we hypothesize the following:

H5: Less than 20% of entrepreneurs utilise many theoretical findings of academics.

H5a: The assessment of the academic work is the same in all the selected regions of Slovakia.

The associations in contingency tables were analysed by Pearson statistics for count data. P-value was being compared with standard a 5% confidence level. P-value which is lower than this confidence level leads to the rejection of the null hypothesis. The null claims there is no association between variables. The calculations were performed in the statistical packages XL Statistics and R. The instruments of descriptive statistics, namely percentages and means were also used.

#### 4 RESEARCH RESULTS AND DISCUSSION

Table 1 presents the results of our research regarding the entrepreneurs' motives for starting a business.

Tab. 1 – Motivation to start a Business in the Selected Regions of Slovakia. Source: own research.

<i>What was your motive for starting a business?</i>	BA in %	TN in %	ZA in %	p-value: BA:TN/BA:ZA/TN:ZA
1. Money	<b>41.18</b>	<b>38.10</b>	<b>48.78</b>	0.6527/0.2263/0.0854
2. I perceive it as a mission	29.41	12.38	10.98	<b>0.0025/0.0001/0.7263</b>
3. I want to have a job	11.76	26.66	21.95	<b>0.0067/0.0357/0.3735</b>
4. I had no choice	3.92	11.43	7.92	<b>0.0434/0.1936/0.3371</b>
5. Other reasons (independence, flexibility, etc.).	13.73	11.43	10.37	0.6171/0.4065/0.7872
p-value* BA:TN/ BA:ZA/TN:ZA			<b>0.0017/0.0010/0.5156</b>	

Notes: \*this p-value compares the structure of all responses, i.e. it examines if there are significant differences within the regions concerning all answers

As it is obvious from Table 1, our research has confirmed the validity of H1. The most important motive for starting a business in the selected regions of Slovakia was money.

H1a was also confirmed. There are no significant variations in the perception of the most important motive among the selected regions (p-value = 0.6527/0.2263/0.0854). At the same time, our research showed entrepreneurs in the Bratislava region stated more often than entrepreneurs in the Trencin and Zilina regions that they had started their own business because they perceive it as a mission (p-value = 0.0025/0.0001).

Our results, however, refuted some findings of for example Podnikajte.Sk (2010) and Iuventa (2012). Nevertheless, we are of the opinion that money as a motivation to start a business is natural and logical and should be given high priority as it supports the main objective of a company. Therefore, we find our results relevant.

The results of research by Belás, Bilan, Demjan, and Sipko (2015) show that the major motive for starting one's own business in the region of Zlin (Czech Republic) is the wish to have a job.

Table 2 contains crucial personal features, skills and abilities of an entrepreneur according to entrepreneurs themselves.

<i>What qualities and skills must an entrepreneur have? (Please give a maximum of up to three answers.)</i>	BA in %	TN in %	ZA in %	p-value: BA:TN/BA:ZA/TN:ZA
1. undeterred by risk	<b>53.92</b>	<b>59.05</b>	<b>51.83</b>	0.4593/0.7414/0.4593
2. persistence	44.12	40.00	38.41	0.5485/0.3576/0.7949
3. creativity	18.63	18.10	27.44	0.9203/0.1031/0.0784
4. imagination	3.92	5.71	7.32	0.5485/0.2585/0.6101
5. expertise	36.27	53.33	50.00	<b>0.0135/0.0285/0.5961</b>
6. quality of education	5.88	4.76	3.66	0.7188/0.3953/0.6527
7. intelligence	9.80	7.62	12.20	0.5755/0.5485/0.2301

8. responsibility	34.31	43.81	46.95	0.1615/ <b>0.0424</b> /0.6171
9. intuition	19.61	12.38	7.93	0.1556/ <b>0.0050</b> /0.2263
10. decisiveness	23.53	21.90	17.68	0.7795/0.2460/0.3898
11. patience	19.61	19.05	17.68	0.9203/0.6965/0.7795
12. optimism	18.63	8.57	8.54	<b>0.0349/0.0151</b> /0.9920
13. other	2.94	1.90	0.61	0.6241/0.1285/0.3222
p-value BA:TN/BA:ZA/TN:ZA				0.2511/0.2372/0.2420

The results of our research confirmed H2. In the entrepreneurs' point of view, the most important characteristic of an entrepreneur is not being afraid to take risks. Other frequently chosen qualities were expertise, responsibility and persistence.

H2a was confirmed as well. We found no statistically significant differences in the perception of the importance of not being afraid to take risks among the selected regions.

The findings within our research are compatible with the conclusions of the presented studies, such as: Knórr, Alvarez and Urbano (2013), Caliendo, Fossen and Kritikos (2014), Ilouga, Mouloungni and Sahut (2014), Deáková, Drážovská, Grznárik and Kondášová (2012), and Soiminen, Martikainen, Puumalainen and Kyläheiko (2012).

We introduce how entrepreneurs think society perceives them in Table 3 below.

Tab. 3 – How Entrepreneurs Think They Are Perceived By Society in the Selected Regions of Slovakia. Source: own research.

<i>Do you think that our society (politicians, public opinion, media etc.) perceives the position and activities of entrepreneurs correctly?</i>	BA in %	TN in %	ZA in %	p-value: BA:TN/BA:ZA/TN:ZA
1. No, our society perceives us negatively	22.55	20.95	15.85	0.7795/0.1707/0.2846
2. Society perceives us incorrectly	41.18	55.24	43.30	<b>0.0434</b> /0.7279/0.0561
3. Society perceives us positively	<b>4.90</b>	<b>1.90</b>	<b>6.70</b>	0.2340/0.5485/0.0735
4. I am not considered it	29.41	21.91	34.15	0.1615/0.4237/ <b>0.0198</b>
p-value BA:TN/BA:ZA/TN:ZA				0.1702/0.5011/ <b>0.0208</b>

It can be argued that H3 was confirmed. Only 6.70% of entrepreneurs in the Zilina region think that society perceives them positively. The numbers in the other regions were even lower, namely 4.90% in the Bratislava region and 1.90% in the Trencin region.

On the contrary, H3a was not confirmed. Whereas the structure of all responses was not different for the Bratislava and Zilina region (p-value=0.1702) and the Bratislava and Trencin region (p-value=0.5011), the calculated p-value (0.0208) implies significant variations in the structure of all responses between the Trencin and Zilina region.

To complement the information it could be stated also that in the Czech Republic (Zlin Region) the entrepreneurs felt their perception by the society on an approximately the same level as businessmen in Slovakia. (Belás, Bilan, Demjan, and Sipko, 2015)

Table 4 is dealing further with the entrepreneurs' assessment of the State's approach, namely of the financial support from the State.

Tab. 4 – The Assessment of the Financial Support of Entrepreneurs by the State. Source: own research.

<i>Do you think the State should</i>	BA	TN	ZA	p-value:
--------------------------------------	----	----	----	----------

<i>support entrepreneurs financially?</i>	in %	in %	in %	BA:TN/BA:ZA/TN:ZA
1. Yes	<b>65.69</b>	<b>67.62</b>	<b>74.39</b>	0.7718/0.1285/0.2301
2. No	22.55	25.71	17.07	0.5961/0.2713/0.0873
3. I don't know	11.76	6.67	8.54	0.2041/0.3898/0.5755
p-value:BA:TN/BA:ZA/TN:ZA			0.4256/0.3128/0.2194	

Since more than 60% of entrepreneurs in all the selected regions stated that the State should support them financially, the validity of H4 was confirmed.

H4a was also confirmed. The calculated test criteria (p-value=0.4256/0.3128/0.2194) indicate no significant differences among the regions regarding this issue. Entrepreneurs in all the selected regions share about the same opinion on whether the State should support them financially or not.

To conclude, we present the opinions of entrepreneurs on the academic sector in Table 5 below.

Tab. 5 – The Application of Theoretical Findings to Real Business. Source: own source.

<i>Do you think the academic sector brings useful solutions for real business?</i>	BA in %	TN in %	ZA in %	p-value: BA:TN/BA:ZA/TN:ZA
1. No, these are far from the real world	43.14	43.81	31.71	0.9203/0.0588/ <b>0.0444</b>
2. Some of the findings are helpful for us	46.08	48.57	56.71	0.7188/0.0910/0.1902
3. We use many theoretical findings in our business	<b>10.78</b>	<b>7.62</b>	<b>11.59</b>	0.4295/0.8415/0.2891
p-value BA:TN/BA:ZA/TN:ZA			0.7269/0.1602/0.1126	

As it is obvious from Table 5, the conducted research confirmed H5. Only 10.78% of the Bratislava region entrepreneurs, 7.62% of the Trencin region entrepreneurs and 11.59% of the Zilina region entrepreneurs declared they use many theoretical findings in their business.

H5a was found possible to confirm as well. The overall structures of all responses were not significantly different among the selected regions (p-values=0.7269/0.1602/0.1126). There was only a partial variation between the Trencin and Zilina region in the first response. Statistically, more entrepreneurs from the Zilina region are convinced that the findings of the academic sector are far from reality.

Generally, entrepreneurs of all the selected regions assess the level of university education relatively negatively. It can be stated that these opinions are based on their own experience because 50% of the Bratislava region entrepreneurs, 51% of the Trencin region entrepreneurs and 47% of the Zilina region entrepreneurs had a university degree within our research.

Consequently, the above mentioned results could be an inspiration to improve the quality of the university education in Slovakia.

## 5 CONCLUSION

The aim of this article was to define, quantify and compare significant attributes of quality of the business environment for SMEs in the selected regions of Slovakia.

Our research showed there are certain regional variations in the assessment of important attributes of the SME segment in Slovakia. Comparing the Bratislava region as the most

economically developed to the other selected regions, we found significant differences in the motivation for starting a business and in identifying vital personal features and skills of an entrepreneur. Certain variations were discovered also in how entrepreneurs think society perceives them and in the entrepreneurs' utilisation of State financial support.

At the same time, there are several factors not significantly influenced by regional characteristics. These is the general State approach towards entrepreneurs, for example the application of theoretical knowledge to business.

The most important finding is that whereas in the most developed region, the region of Bratislava, people usually start a business because they are willing to, in less developed regions, the level of "forced" entrepreneurship is higher.

It also has to be pointed out that entrepreneurs in the Bratislava region stated optimism as a vital quality of an entrepreneur more often than entrepreneurs in the other regions. At the same time, they declared expertise less often than entrepreneurs in the other regions.

Moreover, entrepreneurs assess the State's role in creating business environment rather negatively. They also often believe society perceives them incorrectly. Thus, the research results imply the need to improve the State's approach to entrepreneurship, to create a better image of business activities in the eyes of society and to awaken public interest in conducting business.

Although it is clear that there are certain limitations to our research (e.g. the number of companies involved in the research), we believe that our article has inferred significant incentives for the formation of a more appropriate business environment for SMEs in Slovakia.

Our future research will focus on the examination of the relationships among personal characteristics of entrepreneurs, the propensity to take risks and their financial performance.

## **CREATIVE INDUSTRIES AND THE EU REGIONAL POLICY: A SPATIAL ANALYSIS OF USING STRUCTURAL FUNDS**

*Pavel Bednář, Lukáš Danko, Lenka Smékalová*

### **Abstract**

The creative industries are gaining recognition among countries of the EU, where the regional policy plays a key role in the economic development. However, the relationship between the EU Structural funds and the creative industries is limited specifically to culture, while the concept itself has not been assessed yet. The aim of this paper is to analyse the use of the Structural funds in the creative industries for the programming period 2007-2013. Regression unstandardized residuals were depicted by choropleth maps and multidimensional scaling for spatial analysis of the largest cities by population in the Czech Republic. The findings proved that dominant use of the Structural funds is in the culture sector, while the cultural and creative industries were not specifically supported. Moreover, particular differences were identified in spatial distribution of the creative industries. The results provide a methodological basis for evaluation and further research in conjunction with changing objectives and themes of support from the EU Structural funds in upcoming programming period. Particular focus is put on increasing the proportion of support towards the creative industries and awareness of policy-makers in reduction of spatial disparities in the use of public funds.

### **1 INTRODUCTION**

Currently, the further development of the knowledge intensive society in the Central and Eastern countries (CEEs) is the result of transformation processes of past two decades. The overall process of catching up with Western countries is also reflected in the recognition of the creative industries among CEEs nations. However, in respect both to the European commission and Higgs et al (1998) the concept of culture and creative industries (CCI) was applied for delimitation of object of the paper. These industries are preferably defined (Bakhshi et al, 2013) according to Higgs et al (1998) as “*those industries which have their origin in individual creativity, skill and talent and which have a potential for wealth and job creation through the generation and exploitation of intellectual property*”. Furthermore, development of communities that are attractive to creative individuals provides opportunity for regions to capitalize on diversity and creativity (Acs and Megyesi, 2009). Therefore, regions across Europe are implementing Smart strategies to ensure sustainable development as the result of transforming European regional policies. Encouraging the use of creativity and talent in strategic planning is one of the tools to enhance regional competitiveness. Creative milieu is essential for enhancing regional competitiveness because of their role as the knowledge hubs. Furthermore, it has already become potential catalysts for the development of the CCI and the creative tourism (Kostopoulou, 2013). Production of the CCI is concentrated in particular areas. From a geographical perspective the focus is put on localised production systems that benefit from proximity for communication and exchange (Dahlström

and Hermelin, 2007). However, there is a minimal insight into production processes of the CCI in the Czech Republic. This is due to the fact that the potential of the CCI and culture is often neglected, even though the products of the CCI are a significant part of contemporary economies (Power, 2003; Power, 2010). Mapping of the CCI is essential for further development of this concept. Therefore, it has been acknowledged the assessment of the Creative Indexes by Kloudová and Stehliková (2010) and regional perspectives of performance by Bednář and Grebeníček (2012); Slach (2013); and Danko and Bednář (2013). Furthermore, Bednář (2013) carried out data analysis of tri-sector CCI classification. The support for the CCI is despite previous steps defined rather generally without specific objectives. Thus the aim of the paper is to analyse the impact of the public support on the CCI, based on the ability to receive financial resources of the structural funds in the Czech Republic.

## **2 THEORETICAL BACKGROUND**

The concept of the CCI was identified in 1998 by the Department of Culture, Media and Sport. Specifically, the CCI have their origin in individual creativity, skill and talent (DCMS, 1998). The CCI comprise design, architecture, advertising, games, film, music, publishing, art, performing arts, crafts and toys (Howkins, 2001). Furthermore, the initial definition of the CCI was enlarged with traditional arts industries, design-led industries and branches of new media (O'Connor et al, 2011). Representatives of the CCI are mostly micro and small companies and their products differ, not only on the basis of objective criteria of quality, but also on intangible criteria defined by aesthetics, symbolism, atmosphere and style associated with the product (Puchta, 2010). Place-related production and consumption of the CCI are strongly interconnected (Stryjakiewicz et al, 2014). Furthermore, some areas of production are under control of oligopolies (movies, television and broadcasting), large share of the CCI is represented by micro and small companies (Parkman, Holloway and Sebastiao, 2012). Thus they dispose of potential for job creation through the use of intellectual property. Their economic importance resides in the role as the innovation system (Florida, 2002). The innovative notion of creative individuals provided the basis for formation a new phenomenon called creative class.

The creative class is represented by individuals employed in the CCI. According to Florida (2002) it is not only about the employment itself, but also about the lifestyle of creative individuals in a creative milieu and natural creative clusters. Hence natural clusters have been considered as a spontaneously grown geographical concentration of particular industry, i.e. as a result of economies of agglomeration (Martin, 2008; Yoshino, 2010). Furthermore, Florida (2002) developed the Creative Index (CI), which consists of three particular factors: technology, talent, and tolerance. The CI was used to measure the creative economy in the USA and Canada. Therefore, it was necessary to adjust the CI to measure the creative economy in Europe. Kloudová (2011) unified the previous concept and added measurable index for all European countries with data of the Eurostat with the New Creative Index (NCI). On the contrary, Banks and O'Connor (2009) stress that the economic importance of the creative industries is reflected also in contribution to employment and wealth creation as specific industries. Sharing ideas and information within the creative class are vital factors for further development of social networking (Champion, 2010). These networks work on an informal basis, which empower the access to information (Chapain & Comunian, 2010). However, Peck (2005) and Markusen (2006) assume employees should not be divided into creative and non-creative, because creativity works mostly on non-standardized basis. Moreover, it is a human characteristic, which individuals can apply their unique ideas. Runco

(2007) stress it is related, but distinct from intelligence, imagination, innovation and health. Nowadays creativity appears as a phenomenon based on non-standardized processes.

Non-standardized production of the CCI is often considered as “fuzzy concept”, although it forms a part of local and regional economies. Bell and Jayne (2003) argue there is still lack of compliance between particular CCI and policy to support this concept as an element of competitiveness in cities and regions. Furthermore, they defined urban regeneration, which is connected with economically affected areas (Liverpool, Manchester and Dundee). Competitiveness of regions has recently shifted from traditional hard location factors (infrastructure, taxes) to soft location factors, represented by tolerance and alternative lifestyles (Florida, 2002). The CCI were incorporated into urban planning in communities and works as an element to create cities with artistic background (Phillips, 2004). In particular regions it subsequently led to the creation and development of attractive neighbourhoods, where representatives of production and consumption as the core of the creative economy (Bell and Jayne, 2003). From a geographical perspective, this provides a basis for developing mutual relations of the creative class in urban centres and creative districts. Furthermore, companies in the area learn from each other and benefit from knowledge spillover, which also result in formation of spin-off companies (Wenting, 2008). These areas increase an interaction between market and sharing ideas, which eventually lead into more sophisticated basis for innovation (Turok, 2004). Furthermore, the ability of micro and small companies to persist on turbulent market depends on their capability to come up with new ideas and products. The concept of innovation is currently diversified due to the progressive development of open and non-technological innovation (Caves, 2003). The ability of the CCI (EU) to adapt and develop often depends on targeted public support. The EU introduced the MEDIA programme 2007-2013 with a budget of 755 million EUR to specifically support the audio-visual sector. The programme covered specific areas of production, distribution, training, festivals, promotion, new technologies and international activities.

This paper, however, focuses on a large scale grant schemes of the cohesion policy administered in the Czech Republic through the European Regional Development Fund, European Social Fund and Cohesion Fund. The 2007-2013 programming period officially ended, nevertheless the grant schemes in the Czech Republic are still in the process of drawing. Substantial amount of total Czech allocation has already been claimed by the beneficiaries therefore the first evaluation efforts are appropriate. The cohesion policy in the Czech Republic in the observed period was implemented through number of operational programmes in all three European Union objectives Convergence, Regional Employment and Competitiveness and European Territorial Cooperation. This paper focuses on the first and second named in which 17 individual operational programmes were implemented. The primary sources for support of entrepreneurs at large represented the regional operational programmes of the individual NUTS 2 Convergence regions and most prominently the Operational Programme Entrepreneurship and Innovation also territorially aimed at the Converge regions. The capital Prague as sole region belonging under the Regional Employment and Competitiveness objective implemented two programmes – the Operational Programme Prague – Competitiveness and Prague – Adaptability. Apart from the entrepreneurial support the CCI may have benefited predominantly from Integrated Operational Programme whose projects were used in connection with national institutions focusing on arts and literature.

The efficiency, its measuring, and necessity of public support in general and of cohesion policy in particular are still a keen object of studies focused on both the Czech Republic (Šipikal et al, 2013) and abroad (Marchante and Ortega, 2010; Gómez-García et al, 2010; Dall’erba and Le Gallo, 2007). While there were other studies focused on absorption of public

support in the Czech regions (e.g. Blažek and Macešková, 2010; Hájek et al, 2014), absorption of the EU Structural funds in particular sector of the economy (Smékalová, 2012; Felixová, 2012) and impact of the Structural funds on culture (Žáková, 2013), this paper focuses on impact of the cohesion policy on the whole concept of CCI which is a relatively novel area of research. Furthermore, the aim follows the findings of Žáková (2013) stressing “*There are no overall robust data concerning the financial volume of co-financing by EU Structural Funds in the cultural and creative sectors in the Czech Republic. The number of projects is unknown either. No studies and analyses mapping the use of the Structural Funds for the support of culture have been commissioned by the state or regional authorities*”.

### **3 METHODOLOGY**

The secondary database Bisnode (2014) provided the dataset for quantitative analysis of the CCI. This database offers a comprehensive overview of commercial, non-profit and public entities from publicly available sources for example the Czech Statistical Office and the Ministry of Finance of the Czech Republic. However, it supposed to be noted that the CCIs are assigned to their headquarters because the Bisnode (2014) database does not provide economic indicators for branch entities. An identification of such data would require specific survey of each entity individually. This process requires a long-term efforts and willingness of entities to provide such data.

Furthermore, the dataset excluded those entities, which did not register any turnover or number of employees. These entities were considered inactive as they did not report any activity in last two years. Another step in reducing the final dataset was the ‘bankrupt’ label. The selection procedure of variables from the Bisnode (2014) database for the purposes of quantitative analysis was carried out according to the following steps:

1. Selection of the entity according to the predominant activity within the subgroups of economic activity classification CZ NACE (e.g. the activity accounting for major of the company’s turnover, activities of non-profit or public entities).
2. Registered address of the entity and its identification to the town and region, therefore the administrative level NUTS 3 and LAU 2.

Subsequently, culture sector, cultural industries and creative industries were identified as three major categories of the CCI based on CSO and NIPOS (2014). Furthermore, these categories were divided in specific areas of the CCI with respect to the number of subjects in different subgroups of CZ NACE. However, crafts were excluded from the selection due to difficulties to determine whether products are handicrafts or standardized production without their own creative contribution and innovation. Following tables (1-3) provide an overview of selected predominant subgroups CZ NACE for quantitative analysis:

Tab. 1 - Culture sector. Source: Own elaboration based on Bednář and Danko (2014)

	Predominant subgroup CZ NACE
Photography	74.20
Cultural heritage	47.78, 47.79, 91.03, 91.02, 91.01
Performing arts	90.01, 90.02, 90.04,
Artistic creation	90.03
Arts education	85.52

Tab. 2 - Cultural industries. Source: Own elaboration based on Bednář and Danko (2014)

	Predominant subgroup CZ NACE
Film, television and broadcasting	47.63, 59.11, 59.12, 59.13, 59.14, 60.10, 60.20, 77.22
Music	47.63, 59.20
Publishing	47.61, 47.62, 58.11, 58.12, 58.13, 58.14, 58.21, 63.91,

Tab. 3 - Creative industries. Source: Own elaboration based on Bednář and Danko (2014)

	Predominant subgroup CZ NACE
Architecture	71.11
Design	73.11
Advertising	74.10

Based on findings in Bednář and Danko (2014) a total of 51,929 entities of the CCI were identified based on above defined selection process for quantitative analysis. The culture sector accounted for 21.9%, i.e. 11,395 enterprises, while the cultural industries represent the major part of the CCI with 63.5% (32,999) enterprises and the creative industries with the least representation with 14.5% (7,535).

Ordinary linear regression was employed as the next step of quantitative analysis to determine the relationship between independent variable represented by total/particular number of the CCI/creative entities in municipalities (where condition was city has at least one entity of the CCI) and dependent variable represented by the total/CCI particular category amount of subsidies received from the Structural funds. Municipalities without any entities of the CCI were excluded from the analysis. Hence this paper uses the unstandardized regression residuals, which are successful in excluding very small municipalities by population with high relative concentration of subsidies from the Structural funds (see Faser, Sweeney and Renski, 2005). Eventually, the residuals were portrayed via choropleth maps, where intervals were determined by standard deviation due their normal distribution.

Subsequently, cities over 50,000 inhabitants (including Chomutov with population of 49,784) were selected from the dataset. These respective cities were analysed with multidimensional scaling method that provides the opportunity to reveal distances between objects. Therefore, its role is to reduce dimensions and identify those variables that are crucial for the variability between individual objects in our case selected cities. Simultaneously, its graphical representation allows the user to identify clusters of units based on their similarity represented by values of variables. Furthermore, it also presents perceptual map of individual objects and their distribution in the scatter plot with one to three dimensions, where mutual distances determine not only the position in relation to others, but also presents the relationship to key variables in terms of their variance. These have a major impact on the location of the individual objects in the perceptual map. Multidimensional scaling uses multiple ways of data representation, but the paper focused solely on ALSCAL method, which portrays the distribution of objects (see Hout et al, 2013). From a practical and user point of view it belongs to simple variants of the data representation. Furthermore, this method does not require testing of assumptions such as the normal distribution of values. Even though the method has no special requirements on the used values, it is possible to use factor analysis to eliminate the variables that do not contribute to the differentiation of individual objects. On the other hand, the multidimensional scaling provides this information itself (Jaworska and Chupetlovska-Anastasova, 2009).

## **4 RESULTS AND DISCUSSION**

According to the database the support for the CCI during the programming period 2007-2013 accounted for 4.9 billion CZK as of January 2015, specifically in 101 municipalities out of total 2,987, where the presence of the CCI industries was revealed (i.e. 3.5%). Culture sector absorbed the major part of support, i.e. about of 3.8 billion CZK (76.8%), while cultural industries 0.6 billion CZK (11.9%) and the least amount was present in creative industries 0.6 billion CZK (11.3 %).

Dominance of culture sector is evident, even though its share in the total number of entities in the CCI accounted for 18.2%, i.e. 5838. On contrary, cultural industries accounted for 58.5% on total number (18,806) and creative industries for 23.4% (7,535). Prague achieved the major success in receiving support with 2.6 billion CZK, i.e. 52.6%, followed by Pilsen with 0.6 billion CZK and Brno 0.5 billion CZK. The ranking in second and third place doesn't correspond with neither the number of inhabitants nor number of enterprises in the CCI. Moreover, Prague exhibits its position as the economic centre of the Czech Republic with 11,102 (34.5% of 32,119) active enterprises on its territory. These enterprises received more than half the support. Further analysis revealed that the culture sector reflects dominance of Prague, which is not only the residence of national central institutions in terms of management and development of culture, but also the most important museums, theatres, operas, libraries to name a few. These entities are attractive for both domestic and foreign cultural tourism. Prague contributed in this particular with 0.6%, i.e. 2.4 billion CZK which confirms its position as a centre of cultural life in the Czech Republic. Thus, it is assumed that Prague rather shows characteristics of divergence in terms of support from the Structural funds in the field of culture during the programming period 2007-2013. Furthermore, received support contributed to its increasing cultural importance within the Czech Republic. Culture industries also dominated in the case of Prague, with the share of 21.2% (0.12 billion CZK) from total support in this respective category. Even though Prague is a major centre of film production, broadcasting, music and publishing with nationwide scope, the capital did not achieve the dominant position in this category. Ostrava was ranked second with the share of 17.7% (0.10 billion CZK) and third Mníšek pod Brdy with the share of 12.0% (0.07 billion CZK). In this case it can be deduced that the reason consists in relation to Prague with both proximity and commuter time as this municipality can be considered as a suburban zone of the national metropolitan area. Prague was ranked third in case of creative industries with the share of 14.0% (0.008 billion CZK), while Brno achieved second place with the share of 17.0% (0.09 billion CZK) and Ostrava with the first place with the share of 26.5% (0.15 billion CZK). This ranking is in reverse order compared to the number of inhabitants and the number of enterprises. Ostrava has only 4.0% (237) enterprises in creative industries, while Brno has 8.6% (503) and Prague 30.9% (1808). In this respect, enterprises in Prague remain far behind assumptions.

Another part consist of the spatial analysis of allocations, firstly all CCI together and then in particular categories (see Fig. 1). The values of unstandardized regression residuals were divided into intervals based on multiples of the standard deviation and showed following findings. In case of the sum of allocations in relation to the number of enterprises, the values beyond expectations (>1.5 Std. Dev.) were identified in Prague and its hinterland in the Central Bohemian Region (Mníšek pod Brdy, Tetín) together with the municipality of Dobruška in the proximity to Mladá Boleslav. Other municipalities in this respect are Pilsen, Litoměřice, Rychnov nad Kněžnou that exhibit concentration of animate and inanimate culture. In case of Pilsen there is also the presence of enterprises of the CCI depending on both population and higher art education. These values in case of Ostrava, Opava, Frýdek-Místek where centres of higher art education are present like in Pilsen except the Frýdek-

Místek. Moreover, based on Bednář and Danko (2014) a natural cluster in advertising was identified in the Moravian-Silesian Region. Two cases where both represent centres of Moravian-Wallachian ethnographic region were identified in the Zlín Region – Rožnov pod Radhoštěm and Vsetín respectively. Specific case can be observed in Kralice na Hané nearby Prostějov in the Olomouc Region, where Prostějov was until recently the centre of garment industry with links to design. On the contrary, negative finding of standard deviation ( $<2.5$ ) was identified in the second largest city by population in the Czech Republic – Brno (South Moravian Region) in spite of fact that the city is considered to be a traditional residence of higher art education, cultural institutions including television and radio production and architecture with supra-regional importance. The same results were revealed in other regional capitals such as České Budějovice, Karlovy Vary, Liberec, Hradec Králové, Olomouc and Zlín albeit their importance in the national settlement system. Conversely, the relationship between long-term unemployment rates, decline of traditional industries and low level of support for the CCI from the Structural funds was confirmed in case of municipalities in the Ústí nad Labem Region (see Smékalová, 2012).

Notes:

<sup>a</sup> Regions of the Czech Republic: HP -Prague, ST – Central Bohemia, JC – South Bohemia, PL – Pilsen, KA – Karlovy Vary, US- Ústí nad Labem, LB – Liberec, KH – Hradec Králové, PA – Pardubice, VY – Vysočina, JM – South Moravia, OL – Olomouc, MS – Moravia-Silesia, ZL – Zlín

Support from the EU Structural funds in the case of culture sector (see Figure 2) results above expectations ( $>1.5$  Std. Dev.) are present in Pilsen, in which the motivation to receive support was mainly associated with achieving the status of European Capital of Culture 2015. Other example of municipality being above expectations is Dobruška in the proximity to Mladá Boleslav in the Central Bohemian Region due to restoration of local monuments, primarily the Sugar Museum owned by one of the largest producers of sugar in the Czech Republic. Links to local monuments are also reflected in the case of Rychnov nad Kněžnou in the Hradec Králové Region, Rožnov pod Radhoštěm (Zlín Region) due to renovation of several historical sites of the Wallachian Open Air Museum and in Opava (Moravian-Silesian Region). Value between 0.5-1.5 Std. Dev. was identified in Prague, where similar result with previously mentioned municipalities was expected compared to its importance. Nonetheless, regional centres with significant historical cultural heritage fell behind expectations, namely České Budějovice, Brno and Olomouc.

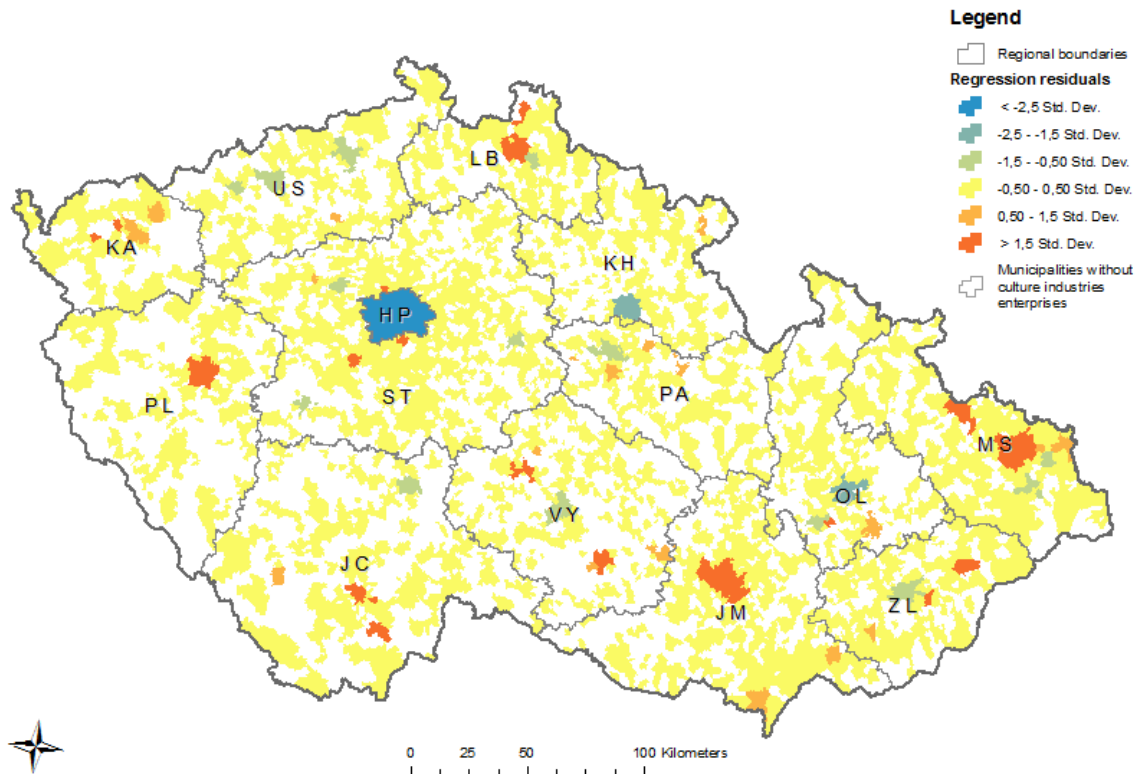

Fig. 3 – Standard deviation of unstandardized regression residuals of number culture industries enterprises and the particular amount of subsidies in the Czech municipalities (2015)

Notes:

<sup>a</sup> Regions of the Czech Republic: HP -Prague, ST – Central Bohemia, JC – South Bohemia, PL – Pilsen, KA – Karlovy Vary, US- Ústí nad Labem, LB – Liberec, KH – Hradec Králové, PA – Pardubice, VY – Vysočina, JM – South Moravia, OL – Olomouc, MS – Moravia-Silesia, ZL – Zlín

Figure 3 represents the culture industries reported the highest number of municipalities reaching  $>1.5$  Std. Dev., compared to other categories of the CCI. The distribution of these values is relatively even in almost all regions (except Prague, Ústí nad Labem, and Hradec Králové Region) even though the culture industries did not receive the highest proportion of support from the EU Structural funds. Subsidies were primarily used by enterprises in publishing in accordance with their amount in relation to other subgroups of CZ NACE in this category. Exceptional values are also evident among municipalities in Prague's hinterland. These municipalities undergo a transformation of suburbanization associated with doing business in the culture industries of wealthy newcomers having higher social status. Thus their activities lead also to commercial suburbanization.

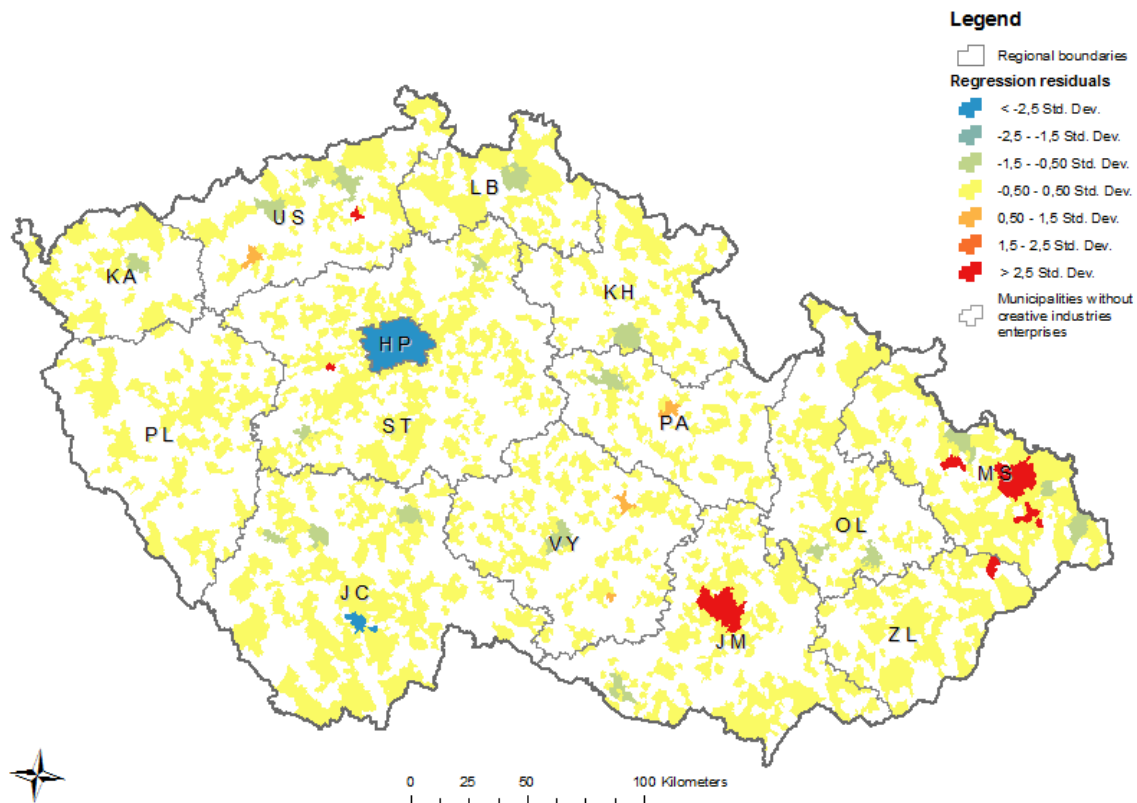

Fig. 4 – Standard deviation of unstandardized regression residuals of number creative industries enterprises and the particular amount of subsidies in the Czech municipalities (2015)

Notes:

<sup>a</sup> Regions of the Czech Republic: HP -Prague, ST – Central Bohemia, JC – South Bohemia, PL – Pilsen, KA – Karlovy Vary, US- Ústí nad Labem, LB – Liberec, KH – Hradec Králové, PA – Pardubice, VY – Vysočina, JM – South Moravia, OL – Olomouc, MS – Moravia-Silesia, ZL – Zlín

Figure 4 depicts the spatial distribution of support in the creative industries, where several values  $> 2.5 \text{ Std. Dev.}$  were revealed. This occurred particularly in Brno (South Moravian Region) and Ostrava metropolitan area (Moravian-Silesian Region). In the first case, this indicator is linked to design and architecture due to presence of university education (see Bednář and Danko, 2014). The second case represents the concentration of advertising as it was mentioned previously (see Figure 1). The relation to architecture was revealed in Rožnov pod Radhoštěm (Zlín Region), which is associated with traditions of the municipality to preserve traditional folk architecture.

Fig. 5 – Optimal distances between the Czech municipalities with population > 50,000 in the two-dimensional stimulus space (2015)

Source: Authors' elaboration based on Regional Information Service and Bisnode

<sup>a</sup> List of municipalities according to population: PRG – Prague, BRN – Brno, OSR – Ostrava, PLZ – Pilsen, LIB – Liberec, OLM – Olomouc, UNL – Ústí nad Labem, HKR – Hradec Králové, ČEB – České Budějovice, PAR – Pardubice, HAV – Havířov, ZLN – Zlín, KLD – Kladno, MOS – Most, KAR – Karviná, OPV – Opava, FRM – Frýdek Místek, KVR – Karlovy Vary, JIH – Jihlava, TEP – Teplice, DEC – Děčín, CHO – Chomutov

Figure 5 represents an analysis of similarity of regression residuals in the CCI among municipalities over 50,000 inhabitants in the Czech Republic. Two dimensions were chosen in the final stage using Euclidean distance due to the value of the S-Stress (0.017). Thus, achieving excellent model's goodness of fit (see Jaworska and Chupetlovska-Anastasova, 2009). Safe power measure to take the square root of the data was used for better readability of the graphic representation in clustering values ranging from -2.0 to 0.0 in dimension 1 and -0.5 to 0.0 in dimension 2. Based on the analysis, values in dimension 1 are determined by the cultural sector. This means that higher values in dimension 1 lead to higher unstandardized residuals in the culture sector. Dimension 2 is formed by values of both remaining categories, i.e. cultural and creative industries. Distribution of selected municipalities provides findings about differences in the four largest cities in the Czech Republic (see Figure 5). Ostrava and Brno dominate mainly in two categories, i.e. in culture sector and creative industries, however, Ostrava demonstrates the highest positive values of regression residuals in both cases. Pilsen differs by significant positive values of residuals in cultural sector, like in the case of Opava. Prague shows similar result, but the values are lower nevertheless. On the contrary, the capital proves the lowest values in culture sector and the creative industries regarding Czech municipalities with particular categories of the CCI.

## **5 CONCLUSION**

In terms of spatial distribution of support towards the CCI from the EU Structural funds in the Czech Republic, the higher concentration in municipalities was discovered compared to identification of their natural clusters (see Bednář and Danko, 2014). Nonetheless, Prague as the capital dominated regarding received support in absolute values. Hence there is a repetitive call for posing a question whether the use of the EU Structural funds contributes to convergence of regions or not. On the contrary, there was a lack of systemic support towards the CCI by the central government during 2007-2013 in each category. These findings correspond with conclusions of Bell and Jane (2003) and Žáková (2013). Consequently, the forceful support of the cultural sector prevails, namely cultural heritage, traditional arts (dance, theatre) and arts educational institutions. The remaining two categories, i.e. cultural and creative industries, are predominately focused on commercial activities, and thus are undervalued. However, they represent key aspects of increasing competitiveness in terms of product or marketing innovations respectively both in the secondary and tertiary sector of the economy. This provides the basis for posing the second question, whether the support of activities in these respective categories of the CCI in Prague is sufficient or not. This is due to the fact that the creativity has been set as one of the objectives within the Strategic plan of Prague. In this regard, the findings endorse a statement that current support towards the culture and creative industries from specialized funds for regions over 125% GDP of the EU average is insufficient. Conversely, it is necessary to admit that many enterprises in culture sector represent traditional national institutions that are accustomed to receive state aid and they have specific staff for project administration. These conditions are often not met in case of private enterprises, which in most cases adopt the status of freelancers and micro enterprises (see Bednář and Danko, 2014).

Regarding added value for the contemporary research the contribution constitutes one of the methods for evaluating the absorption of public support from the EU Structural funds in the realm of the CCI. The paper therefore depicted the spatial distribution of that support. Hence the conducted research provides not only description and explanation of the preceding absorption but also an opportunity to compare the results with data in upcoming programming period. The main reason of such comparison is due to the fact that members of the EU can benefit from large scale programs such as Creative Europe 2014-2020. Simultaneously the EU has introduced Horizon 2020 and Central Europe frameworks that address the issues of cultural heritage and access to cultural goods and services.

The findings also set the basis for subsequent discussion of approaches to the use of these funds to overcome limited systematic attention to the CCI in the Czech Republic during the 2007-2013 programming period. Thus the contribution serves as a stimulus for national and regional policy makers to realize the role of the CCI in the economy. Last but not least, it responds to the request in Žáková (2013) in relation to the project of the Arts and Theatre Institute – Mapping cultural and creative industries (2011-2015), which focuses on the comprehensive analysis and sets procedures for evaluating the CCI in the Czech Republic.

## **COMPETITIVENESS OF BANKING INSTITUTIONS IN THE CONTEXT OF HUMAN RESOURCE MANAGEMENT AND THE CONCEPT OF CORPORATE SOCIAL RESPONSIBILITY**

*Jiří Bejtkovský, Janka Vydrová*

### **Abstract**

The current management concept of human resource management views employees as one of the most significant components of functioning of the entire corporation. Without interested employees, processes and activities cannot be fulfilled, (bank) products or services cannot be provided to clients or customers, performance and competitiveness cannot be achieved. Management has to be cautious in the area of human resource management especially at present times characterized by population ageing. From a long-term perspective, not only 50-employees but also 50+ employees need to be in the centre of attention. However, the idea has not been widely implemented so far.

The aim of this article to reflect this indisputable fact and provoke a debate over the change of perception of the 50+ employees not only in the banking institutions involved which perception is still burdened by myths, stereotypes, and prejudices. Due to the fact that personal know-how of the 50+ employees is not perceived positively and therefore is not duly appreciated, not only a banking institution may lose its image, performance, and competitiveness.

The article presents some of the results of quantitative and qualitative research conducted in banking institutions in the Czech Republic. The discovered facts suggest that the position of the 50+ employees is not positive in the banking institutions involved. This segment of employees is still viewed stereotypically. One of possibilities on how to change this approach seems to be the philosophy of Age Management in direct association with the concept of Corporate Social Responsibility. It approaches every employee not only of a banking institution individually while taking into consideration his/her biological age and changing capabilities.

*Keywords: age diversity of employees, age management, commercial banks, competitiveness, corporate social responsibility, employee 50+*

### **1 INTRODUCTION**

If any corporation wants to be competitive and profitable, it has to offer or produce such services or products in which clients, customers or stakeholders are interested. This thesis applies to all areas of business activity, i.e. also for banking and banking institutions.

A banking institution can be understood as a type of a financial mediator whose main activity is the mediation of the movement of funds between individual economical entities that usually simultaneously participate in active, passive and off-balance sheet operations of a banking institution. In this context, a complex care of a client represents a significant manner of increasing performance of a banking institution. (Belás a kol., 2010)

One of the components that affect the client's satisfaction and therefore loyalty and ultimately also the performance and competitiveness of a specific banking institution is employees with

their level of proficiency, willingness and a proactive approach to clients. Management of a banking institution therefore, within the process of HR management, needs to seek to have the right personnel in the right strategic positions, thus aligning personnel and customer satisfaction and loyalty.

This may help to at least partially mitigate the tendency of decreasing loyalty of clients of large, brick-and-mortar banking institutions towards new, no-fee and low-cost banking institutions. (Nacher, 2014; Urbánek, 2015)

Another fact is that the current world can be characterized as the ageing world full of population tendencies, reversals, and changes. Average life expectancy is getting longer but on the other hand fewer children are born. The number of people of the 50+ age category in the society will soon exceed the number of new-born babies. This will lead to a sharp decline in the labour force. (Eos-llp.eu, 2012; Moseley & Dessinger 2007; Reidl, 2012)

Management and HR managers not only of banking institutions need to take this fact into consideration and create strategic personnel concepts, plans and approaches in the field of human resources management to ensure their corporate processes and activities by skilled, experienced and qualified personnel regardless of their biological age. The aim is to prevent loss of their performance, productivity, competitiveness, and intellectual property, and therefore potential negative impact on economic results of their corporations or banking institutions.

These concepts need to move away from stereotypical perception of the employees of the 50+ group and see them as employees who possess ample working and life experience and may use them in their everyday work when solving their working tasks and obligations.

However Henski (2011) argues that it is more efficient to invest in education, training and development of the 50- employees.

The article focuses especially on social area within the concept of Corporate Social Responsibility because it comprises, besides other things, also care of employees not only of a banking institution. The care should also take into consideration the philosophy of the Age Management – human resource management that takes account of age and changing skills of employees not only of a banking institution, supports age diversity and individuality of every employee not only of a banking institution. Besides other things, the aim of the article is to provoke discussion leading to the elimination of the traditional (classical) approach, i.e. stereotype perception of the 50+ employees which still prevails in the society. This approach emphasizes especially health and social aspects of the 50+ employees in the labour market whereby this age category of employees becomes uninteresting or little perspective for the management not only of banking institutions and the 50- employees are given priority, i.e. employees that are younger, more creative and more flexible. A specific aspect that is not sufficiently appreciated in the traditional approach is the aspect of qualification. The 50+ employees carry personal know-how because they are both personally and professionally mature and have a potential not only for the banking institution that the management should properly appreciate not only e.g. in the process of knowledge sharing but should also seek to ensure that the personal know-how of any the 50+ employee will remain not only in the banking institution also when he/she leaves it.

Within human resource management not only in a banking institution, three basic pillars of personnel work with the 50+ employees could be considered in relation to modern philosophy of the Age Management, concept of Corporate Social Responsibility and as a result of strengthening and increasing performance and competitiveness of a banking institution: the

area of work organization, stimuli of work motivation, and the area of education and development of qualification of the employees. (Bejtkovský, 2013)

## **2 THEORETICAL BACKGROUND**

According to Charouzová (2009), the current concept of human resource management emphasizes especially the following factors: talent management; workforce mobility and flexibility of the labour market; intercultural cooperation; requirements for measurement of all areas of human resource management; new forms in the systems of motivation and benefits; strengthening loyalty and responsibility of employees for their work; outsourcing of some HR activities; use of modern technologies and modern forms of communication; the importance of the Internet labour market; health as an organizational value.

According to Ready et al. (2009) or Guthridge & Lawon (2009), the aim of talent management is to find especially young employees with a high development potential and group them into a team of employees that supports organizational structure and honours personal commitment to the corporate mission. The aim of the process of working with talents is to ensure a required number of young talented employees not only for a banking institution that may fulfil key professional or managerial roles in the future, thus leading to prosperity, performance and competitiveness not only of a banking institution.

Nevertheless, Chulik (2011) in this respect states that the current active workforce is getting old. Children born in 2010 will live at least 10 years longer than those born in 1950. It means that the number of elderly people approaching retirement age will be increasing.

Population ageing and the entire demographic development are facts that need to be specifically regarded, accounted for, and reflected not only in the area of HR management both in the macroeconomic and microeconomic level and without stereotyping. (Hansen Čechová, 2012; Kutschera, Vodešilová, Fialová & Kubešová, 2012; Žnidaršič, 2010)

Anyway, most Czech and Slovak organizations still prefer 50- employees and hesitate about employing 50+ employees. (Čopjaková, 2012)

Broderick (2009) focuses on the organization's approach to the 50+ employees in Australia and states that there is age discrimination in employment of illegal, yet it is quite common.

According to Brandon (2011), the share of the 50+ employees is in some organizations greater, in others organizations less. The proportion depends on the type of work that the 50+ employee performs.

Whereas the generation of the 50+ employees (Baby Boomers) can be characterized as employees who have strong work ethic; know-how in work procedures and processes; they are loyal not only to the banking institution; they have strong personal responsibility; they analyse from a long-term perspective; risk less; are slower when fulfilling their work tasks; use formal communication more than the 50- employees. (Hawley, 2009)

The 50+ employees strive for the same goals, values and things like the 50- employees. (James, McKechnie & Swanberg, 2011; Rothwell, Sterns, Spokus & Reaser, 2008; Shea & Haasen, 2006)

The above-mentioned facts imply that the current philosophy of talent management cannot focus especially on young employees in a long-term perspective but should target employees of all age groups who work not only in the banking institution. To ensure strategic fulfilment and successful implementation of the idea not only into banking practice, the management of corporations should understand the benefits of Age Management which may have a positive

effect on and strengthen performance, image and competitiveness not only of a banking institution thanks to, besides other things, age diversity and acceptance of personality of every employee.

If the management not only of a banking institution endorses and honours the principles of the CSR concept, the Age Management philosophy can be found in a certain form in social area that focuses its activities especially on the area of human resource management.

Regard to the fact that Corporate Social Responsibility is an abstract concept in a certain extent; no one could accurately define its borders yet. It does not exist any uniform definition. (Burianová & Paulík, 2014)

In general, key areas of the CSR concept can be divided into three basic pillars: economic area (principles of good management; code of ethics; transparency; rejection of corruption; behaviour to customers, suppliers, investors; relations with shareholders; intellectual property protection; ethics of marketing and advertising), social area (health and safety of employees; development of human capital and education of employees; work-life balance; corporate philanthropy and volunteering; equal work opportunities; diversity in the workplace; outplacement and retraining; listening to and dialogue with various target groups – e.g. stakeholders), environmental area (environmental corporate policy; environmental management; protection of natural resources; mitigation of negative impacts on the environment; investments in clean technologies). Responsible business in various forms is commonplace nowadays to many not only banking institutions. (Pavlík & Bělčík, 2010; Petříková, Hofbruckerová, Lešingrová & Hercík, 2008)

The article will further refer to social area of the CSR concept that is in direct relation to human resource management not only in a specific banking institution.

### **3 OBJECTIVE AND METHODS**

The aim of the article is to highlight the importance and non-underestimation of the process of population ageing, and thought-forming in the area of strategic management of human resources not only in banking institutions that will be free of prevailing stereotypes and prejudices towards the 50+ employees so as to prevent decrease of their performance and competitiveness.

Partial objectives of the article include:

- Verification of hypotheses (H1, H2) and answering research questions (RQ1, RQ2, RQ3) associated with the area of strategic management of human resources in banking institutions.

The article presents a view of some of the results of quantitative and qualitative research conducted in banking institutions in the Czech Republic. The aim of the researches includes without limitation:

- Identification of what activities the banking institutions performs in social area within the concept of Corporate Social Responsibility.
- Identification of basic characteristics of the 50+ employees from perspective of management of a banking institution as well as the 50+ employees themselves.
- Verification to what extent the banking institution cares of age diversity of employees and individuality of every employee.

- Identification of the fact whether the banking institution cares about maintaining knowledge and experience of the 50+ employees (their personal know-how) in the banking institution even after they leave it.

On grounds of an analysis of domestic and foreign expert resources, two hypotheses and three research questions have been formulated:

- H1: The perception of selected characteristics of the 50+ employees is consistent in respondents – the 50+ employees and HR managers of banking institutions.
- H2: Perception of the effort of the management of banking institutions to maintain the personal know-how of the 50+ employees even after they leave the banking institution is not identical in the respondents – employees 50+ and HR managers.
- RQ1: Why is the amount of job opportunities for the 50+ employees smaller than for the 50- employees?
- RQ2: How can the philosophy of Age Management contribute to the increase in performance and competitiveness of banking institutions?
- RQ3: Can it be stated that the improvement of perception (image) of banking institutions can be due to the CSR concept in direct relation to the implementation of the philosophy of Age Management?

Employees of banking institutions that are active in and responsible for the area of human resources (HR managers, specialists or leaders) and employees of banking institutions from the 50+ age category were confronted with these hypotheses and research questions.

When choosing appropriate research methods for the implementation of the defined objectives, several aspects were taken into consideration. It was considered whether the selected methods will ensure truthfulness of respondents' answers and contribute to the achievement of the objectives defined. From research methods, questionnaire survey and observation were used. These methods were further supplemented with a semi-structured interview with the employees of banking institutions.

Within the performed quantitative and qualitative research, five banking institutions were addressed: Česká spořitelna, a.s.; Československá obchodní banka, a.s. (including Era – Poštovní spořitelna); Komerční banka, a.s.; GE Money Bank, a.s. and Raiffeisenbank a.s.

The respondents were employees of headquarters in the Czech Republic, branches and client centres. The research group of the questionnaire survey included in total 180 employees of banking institutions working in and responsible for the area of human resources management (82 females and 98 males) and 282 employees of the 50+ age category (128 females and 154 males). The respondents age structure (the 50+ employees) is presented in a table (Tab. 1).

Tab. 1 – The respondents' age structure (the 50+ employees). Source: own source

<b>The employees age 50+ (interval)</b>	<b>The absolute frequency</b>	<b>The relative frequency</b>
50 – 54	208	73.76 %
55 – 59	54	19.15 %
60 – 65	20	7.09 %

Verification of the validity of hypotheses was performed by using the McNemar test of symmetry and Stuart test of homogeneity of marginal probabilities. The research group of the

semi-structured interview included 20 employees of banking institutions working in and responsible for the area of human resources management. By means of the interview, more general categories were defined that covered statements of the addressed employees and consequently it was identified what claims were repeated in their responses. At the end, summary and interpretation of the identified facts was performed.

## 4 RESULTS

Loyalty and satisfaction of clients with the banking institution is, besides other things, expressed also by the willingness to purchase and use their products. (Belás, Holec & Homolka, 2013)

So, to have a satisfied and loyal client, a banking institution needs to have experienced, educated, willing employees with information and communication skills. It is because this is the place of a direct contact of the employee and the client. In association with the process of population ageing and stereotype perception of the 50+ group of employees, twelve characteristics of the 50+ employees were identified in which the level of consistency of the responses of employees of banking institutions working in and responsible for human resource management (HR managers) and of the 50+ employees was investigated. The responses of the 50+ employees are expected to be the same as those of their HR managers. Verification of validity of the H1 hypothesis was performed by using the McNemar symmetry test.

H0: responses to selected characteristics of the 50+ employees from respondents are symmetrical.

HA: responses to selected characteristics of the 50+ employees from respondents are unsymmetrical.

The calculation was made using the following equation:

$$\chi^2 = \sum_{i < j} \sum \frac{(n_{ij} - n_{ji})^2}{n_{ij} + n_{ji}} \quad (1)$$

If the p-value is  $< \alpha$ , the H0 hypothesis is rejected in favour of the HA hypothesis and on these grounds, the H1 hypothesis is rejected. Value  $\alpha = 0.05$ . Results of selected characteristics of the 50+ employees in banking institutions by means of the McNemar symmetry test are specified in a table (Tab. 2).

Tab. 2 – Verification of the H1 hypothesis by means of the McNemar symmetry test. Source: own source

Characteristics	p-value	Verification
Reliability	0.480e-08	The H0 hypothesis is rejected in favour of the HA hypothesis and on these grounds the H1 hypothesis is rejected.
Experience	0.003820	The H0 hypothesis is rejected

		in favour of the HA hypothesis and on these grounds the H1 hypothesis is rejected.
Loyalty	1.282e-04	The H0 hypothesis is rejected in favour of the HA hypothesis and on these grounds the H1 hypothesis is rejected.
Willingness to share his/her acquired experience (personal know-how)	0.528e-08	The H0 hypothesis is rejected in favour of the HA hypothesis and on these grounds the H1 hypothesis is rejected.
Ability to use his/her intuition in a greater extent	0.00840	The H0 hypothesis is rejected in favour of the HA hypothesis and on these grounds the H1 hypothesis is rejected.
Willingness to further education	6.210e-06	The H0 hypothesis is rejected in favour of the HA hypothesis and on these grounds the H1 hypothesis is rejected.
Ability to work with a computer in order to fulfil the required tasks	1.322e-12	The H0 hypothesis is rejected in favour of the HA hypothesis and on these grounds the H1 hypothesis is rejected.
Language skills required to perform a job	4.012e-08	The H0 hypothesis is rejected in favour of the HA hypothesis and on these grounds the H1 hypothesis is rejected.
Slower pace of work	2.800e-06	The H0 hypothesis is rejected in favour of the HA hypothesis and on these grounds the H1 hypothesis is rejected.
Adaptability to technological changes	8.022e-14	The H0 hypothesis is rejected in favour of the HA hypothesis and on these grounds the H1 hypothesis is rejected.
Lower self-esteem and self-confidence	0.02466	The H0 hypothesis is rejected in favour of the HA

		hypothesis and on these grounds the H1 hypothesis is rejected.
The tendency to stereotyping and the selection of his/her proven solution	6.628e-02	The H0 hypothesis is rejected in favour of the HA hypothesis and on these grounds the H1 hypothesis is rejected.

In all selected characteristics of the 50+ employees the level of consistency of the answers of the HR managers and of the 50+ employees involved differed. The H1 hypothesis has therefore been rejected on grounds of the evidence obtained. It can be generally stated that the data obtained from the respondents are unsymmetrical.

The concept of Corporate Social Responsibility can be understood as a program to maximize profits not only of a banking institution and at the same time increase satisfaction of all participating entities. (Belás, Burianová, Cipovová & Červenka, 2013)

To maximize profits of corporations, it is necessary to align and put in interaction all resources that the banking institution has. It means financial, information and material resources. The mutual interaction can be ensured in a targeted and efficient manner only by employees that have ample working and life experience, which are namely the 50+ employees. That is why the management not only of banking institutions should seek to maintain the personal know-how of the key employees in their company in a certain form also after they leave the corporation. This assumption was part of the H2 hypothesis. The hypothesis was verified on grounds of the homogeneity test of marginal probabilities (Stuart test). Data were organized in matrices same as in the case of the H1 hypothesis. Since the requirements for the symmetry test analysis were not fulfilled, the Stuart test of homogeneity of marginal probabilities was used.

H0: marginal probability of lines and columns are the same.

HA: marginal probability of lines and columns are not the same.

Results of the verification of the H2 hypothesis are provided in a table (Tab. 3).

Tab. 3 – Verification of the H2 hypothesis by means of the Stuart homogeneity test of marginal probabilities. Source: own source

Statistics of the Stuart test	Q – statistics = 102.8082
Critical value	8.4420
Lines (marginal frequency)	42 68 98 52 22
Columns (marginal frequency)	58 132 58 20 14

$Q \geq \chi^2_{1-\alpha}(k-1) \Rightarrow H_0$  is rejected. On grounds of the Stuart test of homogeneity of marginal probabilities, the H0 hypothesis is rejected on the 5% significance level in favour of the HA hypothesis. This is the evidence that supports the H2 hypothesis. It can be generally stated that the perception of the efforts of the management of banking institutions to maintain the

personal know-how of the 50+ employees even after they leave the banking institution is not identical in the respondents – employees 50+ and HR managers.

According to the addressed employees of banking institutions working in and responsible for the area of human resource management, the amount of job opportunities for the 50+ employees can be generally characterized as lower due to their lower pace of work and performance, increased difficulty in dealing with changing requirements for professional knowledge, sometimes worsening health condition, or lower interest of corporate management in this group of employees in the labour market especially due to preferring the 50- employees.

The philosophy of Age Management could contribute to increase of performance and competitiveness of banking institutions thanks to its approach that takes into consideration age, changing capabilities, potential, and individuality of every employee not only of a banking institution. Implementation of Age Management is broad and covers all age groups of employees from graduates to retirement age employees who work in the banking institution. Nevertheless to perceive the philosophy as efficient and targeted, elimination of stereotype perception not only towards the 50+ employees is required. In direct association with the social area within the CSR concept, equal opportunities for all age groups of employees in banking institutions can be considered within education and professional development along with care of health of all employees, flexible working time (shift management according to employee's suggestions), work-life balance or development of the working environment and ergonomics of work for all employees of banking institutions.

Performance and effective work style in this respect are also supported by the development of intergenerational cooperation. Working teams not only on the level of headquarters but also branches and client centres seem to be beneficial if there is heterogeneity in age. Employees learn from each other, share professional experience, knowledge, develop soft-skills and stimulate each other to more efficient performance of work assignments.

According to the addressed employees of banking institutions working in and responsible for human resource management, the philosophy of Age Management as well as the concept of Corporate Social Responsibility may to a certain extent improve perception and image of the banking institution. It also depends on what working position needs to be occupied at that moment. Nevertheless it cannot be stated it is thanks to the two concepts. There is a varied range of internal and external entities actuating on every banking institution that strengthen or weaken the overall perception. Potential employees decide on the possibility of seeking employment at a banking institution concerned having taken into account complex perception of all the effects.

## **5 DISCUSSION**

One could expect that the perception of selected characteristics of the 50+ employees of banking institutions will be identical among the employees and HR managers, specialists or leaders. Nevertheless, the assumption has not been confirmed by the qualitative research. Inconsistency and variability of respondent's answers can be presented especially through prejudices and stereotype perception mainly of HR managers. Since the questionnaire survey was completely anonymous, the 50+ employees did not have a reason to positively improve their responses. The qualitative research revealed that the 50+ managers are less burdened by stereotypes or prejudices. This is also obvious due to the fact that they are in everyday contact and there is immediate feedback. Therefore, a question arises whether every potential employee is really approached on an individual basis according to the scope of a job analysis within an admission procedure in a banking institution?

Some 50+ employees are worried to share their personal know-how because of a potential loss of their current working position which may be one of the reasons of the different perception among respondents. Here, a mistake could be sought not only in banking institutions but also in the labour market itself. Another reason for different perception is the fact that the personal know-how can be shared within teamwork which is not realized by some of the respondent. Some banking institutions use experienced employees 50+ at the position of a lecturer, mentor or coach for the development of the 50- employees. On the other hand, the 50+ employees often feel lack of interest or non-appreciation of their personal know-how. So where to find inspiration on how to work in efficient and targeted manner with the 50+ employees and their personal know-how not only in banking institutions?

In association with the process of population ageing, the management not only of banking institutions will have to understand and accept the 50+ employees despite their weaknesses if they want to ensure processes, activities and services for their clients also in the future. Therefore, a question arises whether the amount of job opportunities for the 50+ employees will be on a satisfactory level in the next years.

To ensure positive perception of the implementation of the philosophy of Age Management not only in a banking institution, all employees need to be informed on the entire concept and associated benefits. Then, every employee should feel their personal contribution for the banking institution that will be appreciated in a specific way and should not feel discrimination tendencies. An advantage for a banking institution may manifest itself in increase of performance and competitiveness since it will have employees that are loyal, satisfied and motivated. Despite undoubted benefits of the Age Management concept, why hasn't it been implemented in all banking institutions so far?

If not only banking institutions want to make use of the external labour market within the process of hiring employees, the fact that they implement the CSR concept in direct relation to the Age Management philosophy is very positive. Nevertheless, strategy based on addressing new employees will not do with mere two variables. The management not only of a banking institution therefore needs to think in a broader context.

Employers believe that their corporate policy, culture and practice are neutral in respect of age (non-discriminating). They perceive it as a laudable approach. At the same time they admitted that they preferred the 50- employees when recruiting employees in a team and that they ensured not to dismiss an employee just before the retirement age. Employers are not well informed on the usefulness of work with the 50+ employees and on appropriateness of investments in them. At the same time they think that they have sufficient access to information and do not see connection between profitability and Age Management. (Bosničová, 2012)

## **6 CONCLUSION**

The article was focused on a certain manner of evaluating and working with the 50+ employees in banking institutions. The issue becomes increasingly important especially in association with the process of population ageing and later retirement. If the management not only of banking institutions will prefer the 50- employees, performance and competitiveness of a business entity cannot be ensured from long-term perspective. Due to stereotype perception of the 50+ employees, lower interest prevails in such employees not only in banking institutions. This fact is mentioned in the article not only as theory but has also been confirmed by the research part.

The comparing studies focusing to the 50+ employees in banking institutions have not been realized yet. That's why the results of our research were compared to generally published researches to the topic of 50+ employees.

Two hypotheses have been formulated and three research questions were determined by means of the analysis of expert resources. On grounds of verification of the validity of hypotheses it can be said that the view of HR managers addressed by the banking institution differs from perception of the 50+ employees of themselves. Compliance within selected characteristics of the 50+ employees is higher when comparing an immediate superior and the 50+ employee. In some banking institutions, personal know-how of the 50+ employees is shared by means of mentoring, coaching, or project-based work. Not all the 50- employees consider this form of knowledge and experience sharing to be beneficial. On the other hand, the 50+ employees worry about the loss of their job if they share their personal know-how.

To eliminate stereotype perception and prejudices towards the 50+ employees not only in the addressed banking institutions, the ability to work with every employee in efficient and targeted manner is required. To see every person as an individuality with different biological age and changing skills. This thesis is an assumption of the Age Management concept. An advantage of the philosophy is the fact that the concept considers the same approach to all age categories of employees. This should prevent positive discrimination of some employees. Within the process of recruiting, it is positive if a corporation implements the Age Management philosophy in direct association with the CSR concept. Nevertheless, the cooperation needs to be perceived deeper and also other variables need to be taken into consideration that influence perception of the banking institution in the area of HR activities.

The philosophy and selected principles of management by Tomas Bata are also worth mentioning that enable increase of corporation performance and satisfaction of employees. (Culík, Končítiková & Staňková, 2014)

If not only a banking institution has experienced, motivated, satisfied, loyal employees of heterogeneous age, it has a potential that all activities, processes or services for bank clients will work efficiently, which in turn will be reflected in overall performance and competitiveness of the banking institution in short-term as well as long-term perspective.

## **STUDENTS' ATTITUDE TOWARDS TAKING RISK AND STARTING UP BUSINESS WITHIN THE CONTEXT OF THE SOURCE OF RECEIVED INCOME**

*Tomasz Bernat, Aleksandra Gąsior, Rafał Nagaj, Piotr Szkudlarek,  
Małgorzata Zakrzewska*

### **Abstract**

Considering the issue of students' sources of income it is worth noticing that it is considerably easier, more comfortable and better for the youth to educate until they reach the age of majority – from the youth's viewpoint, rather than after the age of eighteen. Yet, it is not so easy in case of people who are over 18 years of age and have made a decision to continue their education. Completion of compulsory schooling gives an opportunity to study at the university. However, sources of income at the young person's disposal might allow further education or, on the contrary, limit the access to it. Therefore, a young adult needs resources which may allow him to live out of the family home, often in the place where the costs of living are higher than by the parents. In addition, there are privately-run educational facilities, where one has to pay fees even for full-time courses. A lot of questions related to this issue arise.

How do the youth, beside the major source of income being the parents, finance their education at the university? Are there any impulses stimulating the youth to start their own businesses? What risk is the possible entrepreneurship of students starting their own businesses burdened with?

The authors will do their best to give an answer to the questions raised above, in the article below which contains theoretical aspects. Moreover, the answers will be supported by the outcome of research done with using poll and experimental methodology.

*Keywords: entrepreneurship, incomes, students*

## **1 INTRODUCTION**

Considering the issue of students' sources of income it is worth noticing that it is considerably easier, more comfortable and better for the youth to educate until they reach the age of majority – from the youth's viewpoint, rather than after the age of eighteen. Article 70 of the Constitution of the Republic of Poland guarantees the rights to education, where it is compulsory till 18 years of age. The fact that education in public school is free of charge, which allows any young person to receive secondary education, is an advantage of the Polish system. It is worth noting that Poland abandoning the socialist system after 1989 allowed the option of providing educational services which are also payable. It should be remembered, however, that the form of education (free of charge or not) chosen for the children is the parents' personal choice. It should also be noted that in random cases, which caused difficulties for the child to 18 years of age to acquire knowledge The Polish State has numerous mechanisms which might be implemented to help the minor to educate.

Yet, it is not so easy in case of people who are over 18 years of age and have made a decision to continue their education. Completion of compulsory schooling gives an opportunity to

study at the university. However, sources of income at the young person's disposal might allow further education or, on the contrary, limit the access to it. In spite of the fact that education at State universities on full-time courses is free of charge (part-time programs are payable), it is often connected with leaving the family home and moving to larger cities. Therefore, a young adult needs resources which may allow him to live out of the family home, often in the place where the costs of living are higher than by the parents. In addition, there are privately-run educational facilities, where one has to pay fees even for full-time courses. A lot of questions related to this issue arise.

How do the youth, beside the major source of income being the parents, finance their education at the university? Are there any impulses stimulating the youth to start their own businesses? What risk is the possible entrepreneurship of students starting their own businesses burdened with?

The authors will do their best to give an answer to the questions raised above, in the article below which contains theoretical aspects. Moreover, the answers will be supported by the outcome of research done by scientists from Faculty of Economics and Management of Szczecin University.

## **2 DEFINITION OF ENTREPRENEURSHIP**

It is worth noting that "economic historians claim that from time to time we deal with waves of entrepreneurship in the world economy (e.g. in the second half of the XIXth century in Europe and North America.)The 80s.and 90s. may also be such a wave. It caused the renaissance of entrepreneur and entrepreneurship in the economic theory. A number of papers on the subject appeared which went beyond traditional economics" (Gruszecki, 1994) It follows that entrepreneurship has its ups and periods of stagnation, as far as an interest in it is concerned. However, we cannot fail to point out the authors who took a challenge of creating their original definition of entrepreneurship. J. Reykowski(Reykowski, 1986) may be enumerated as one of the first authors who focused on entrepreneurship in the 80s. He claimed that entrepreneurship is a set of characteristics which particularly define actions of: teams of people, institutions and the entire economy as well. E. Otoliński defined entrepreneurship in a similar way (Otoliński, 1996). M. Bratnicki is another author who may be enumerated. He presents it as a process linking opportunities and actions for socially responsible wealth within the context of mutual evolution of people together with its environment (Bratnicki, 2004). According to K. Jaremczuk entrepreneurship is "a certain social-economic force, the force not only of economic dimension, but also individual, social, cultural" (Jaremczuk, 2003).

The definition of entrepreneurship varies from the fields of study. Kirzner (1979) defined entrepreneurship as the process of creating something new with value by giving the necessary time and effort assuming financial, psychic and social risks and receiving the resulting rewards of monetary and personal satisfaction and independence. For others, entrepreneurship works like an engine in for economic development, job creation and social adjustment for developing countries (Alam, 2009). Furthermore, entrepreneurship is a process of opportunity identification and the creation of an organization to exploit the opportunity (Nandamuri, Gowthami 2013). Therefore, entrepreneurship contributes income, jobs, R&D innovations, generating economic benefits that are often larger than the private benefits reaped by the entrepreneurs themselves (Van Praag and Versloot, 2007). Consequently, entrepreneurship is perceived as a method to achieve a superior position by utilizing a high level of creativity (Bulut, 2010).

It is worth adding that entrepreneurship is treated not only as an attitude, but also as a process. entrepreneurship considered a process consists in creating and developing companies (Kapusta, 2006). However, it is important that different approaches of authors indicate that entrepreneurship cannot be separated and related only to the organization or only to the man. There are nearly as many definitions characterizing entrepreneurship as authors dealing with this issue. Nevertheless, it may be stated that entrepreneurship always means some sort of creative restlessness, which prevents being satisfied with the current state of affairs and leads to change (Jacher, 1999). However, discussions on the search of the most universal definition of entrepreneurship focus on the following aspects (Borowiecki and Siuta-Tokarska, 2008):

- searching for new ideas,
- transforming an idea into a market effect,
- looking for new forms of allocating resources,
- activating motivations among the participants,
- superiority of the personality of the company founder,
- building a network of dependences with the environment,
- taking people and process into consideration,
- setting new values,
- tendency for risk.

Tendency for risk referred to above, as one of the aspects the authors on the subject discuss, will also be one of the factors that will be analyzed in the research presented in the article below.

### **3 ENTREPRENEURIAL INTENTIONS**

Entrepreneurship can be studied from different perspectives. Researchers have identified different kinds of factors that influence entrepreneurship. Prior to Bowen and Clercq these can be economic freedom, regulatory environment, quality of government, political stability (Bowen and Clercq, 2006). Entrepreneurship has its roots in intentions. For Bird (Bird, 1998) entrepreneurial intentions are a *state of mind*, which guides and gives direction to individuals towards formulation of new business concepts. Analysis conducted on determinants of entrepreneurial intentions exposed that a few factors, identified to individual characteristics and grouped into 3 categories: self-efficacy, personality, and family background of individuals. The first two categories are often specified as internal entrepreneurial intentions. They consist of e.g. personality dimensions (Akanbi, 2013) (Gartner 1988), gender differences (Marlow and Patton 2005), planned behavior (Markan, Balkin& Baron, 2002)(Souitariset 2007), personal entrepreneurial experiences (Rajiman 2001). The last one – family factor- is seen as an external one and should be took into detailed consideration when discussing the aim of this paper.

According to familial factors one should focus on family history of entrepreneurial activities, where family business constitutes important impact on entrepreneurship (Carr and Sequira, 2007). Consequently, children who were grown up by entrepreneurial parents have a bigger chance for entrepreneurial career (McElwee, Al Riyami (2003). Taking into account the aim of this article, one should notice that one of the direct factors that influences the entrepreneurial intentions are the financial resources in the family. Entrepreneurial family members can become a symbol of entrepreneur and source of financial and non-financial help (Ahmed, 2010), often needed to start-up a new business. Consequently what affects the entrepreneurial intentions are parental occupation and family financial status.

On the contrary, as it goes with self-employment, it is directly correlated with student's own entrepreneurial attitude. One can distinguish two different types of individual's entrepreneurial attitudes in motivation to start ventures. One becomes an entrepreneur<sup>3</sup> as consequence of its necessity (*necessity entrepreneur*) (Bulut, 2010). The other (*opportunity entrepreneur*) starts its business in order to pursue possibility (Block, Wagner 2010). These attitudes can be often correlated with personal income and financial status.

#### **4 STUDENTS' INCOME IN THE CONTEXT OF THEIR ENTREPRENEURIAL INTENSIONS**

As written above, one of the external factors of entrepreneurial intentions is the financial support, mainly given by the family members of potential entrepreneur. Taking into account students as a research group of this paper, their income can be divided into three categories: family support, state/ university/company support and own income.

Family support, as presented before is included in external entrepreneurship factors. Second category – from the point of view of state support - includes e.g. a) council tax that it is set by local councils to help pay for local services. In general full-time undergraduate or postgraduate students, whether they live in private property or University residences, are exempt from council tax; b) housing benefit, which helps pay rent whether one reside in private, housing association, student or local authority accommodation. It is mostly eligible for part-time students; c) income support - is a benefit intended for people who cannot normally work (or who work fewer than 16 hours a week), and who are on a low income and fall into one of the categories. It is mainly eligible for part – time students and d) maternity benefits for students that become pregnant during their studies.

Universities make various payments to students for tuition and fees, teaching, research, and other education-related activities. This policy addresses types of payments made to both graduate and undergraduate students, including scholarships, fellowships, stipends, prizes and awards, compensation for services, drawings, refunds and reimbursements.

For example, according to the *Basic Rules of Entitlement*, to qualify for Income Support students must meet following requirements: be in the relevant group who can claim for the supports; be in not paid work, be not entitled to Job Seekers Allowance or Employment Support Allowance ; their income is sufficiently low. As seen above, university rules are coherent with those given by the State and students to receive one must fulfill the requirements.

In a number of universities, students are cooperating with different kinds of businesses, industries, research organizations, and governmental agencies located all over the countries, winning accolades (and frequently future jobs) from employers everywhere. Students, while on the job, are supervised by the employer and are subject to all regulations of the company by which they are employed and all applicable labor laws. Cooperating students gain experience with many of the most successful corporations in the country. E.g. companies like Procter & Gamble, Boston Scientific, and Dow are among cooperating employers. Additionally, there are offered programs with an international option that enables students to cooperate abroad in great countries in Europe and Asia. With this program, engineers can complete the same 5-year curriculum and gain valuable experience in the global marketplace.

There are also scholarships given by different kinds of companies. The most popular are those developed by companies from bank and industry sector. They consist both of financial support and internships programs The most popular students paid activities during their

studies are e.g. campus brand manager. Big companies – including Apple, Reckitt Benckiser, banks, and law and accountancy businesses – pay a few students to represent their brand at universities. This usually means putting up posters, running events and talking up the firm to fellow students.

Giving an example of self-employment activities the most popular are private tutoring, when students advertise their skills at a local school or community center and consider themselves teaching pupils for different kinds of exams and foreign language certificates. Other example is online PR activities. Internet access gives a wide range of *Web* work opportunities. Students with their web-savvy abilities gives support to companies PR activities on different kinds of social media and website IT management. A lot of interest is also paid to “manual labor”. Students advertised themselves e.g.as a cleaner, painter, gardener, heavy-goods mover etc.

These kinds of work on one side are not very well paid, on the other side can be also seen as a first steps of entrepreneurial activities.

One of the intentions which may be considered a motivator to accept the challenge of creating a company are sources of income. Characterizing the Polish conditions, among students’ sources of income, parents (family e.g. grandparents (LIT), godparents older siblings) ought to be enumerated in the first place. However, if the relatives are not able to sustain the student, there are other possibilities which are offered by the State institutions or private sector.

Considerations relating to the sources of income should be started from the possibilities offered by the very public universities. Regulations which each unit is obliged to present formally in its provisions are an example. Taking University of Szczecin (UniwersytetSzczecinski) as an example, all information concerning granting material support is included in the “Rules of Procedure and criteria of granting material support to the students of University of Szczecin” which is announced annually. The following possibilities offered by the State institutions may be found in it:

- accommodation grant
- a special grant for disabled persons
- Rector’s scholarship for the best students
- minister’s scholarship for outstanding achievements
- financial aid

It means that the public authorities make every effort to create and support systems of individual financial and organizational support for students. An interesting study was done by students from Koło Naukowe Ekonomistów at Szkoła Główna HandlowainWarsaw. They conducted a research on “Students’ income sources and an assessment of the system of granting financial support at WydziałNaukEkonomicznych SGGW in Warsaw (Świtlińska and Roman, 2011). It shows that 60% of students become gainfully employed during studies, but also  $\frac{3}{4}$  of the studied population were regularly financed by the family, 16% responded that they receive financial aid from the family from time to time, and there is a group of 14% who did not get any financial help from the relatives.

Nonetheless, it is not the only way the students can select. Private sector has a wide array of job offers for students of full time courses. Thereby, students start work during the academic year but also accept seasonal work in Summer. There are also individuals who start up business and simultaneously study on full time courses. There are also students who are business partners in family businesses and study on full time courses as well. It should also be borne in mind that it is not only the unfavorable material situation that forces the students to work during studies. Every so often, through their entrepreneurial actions, the students in a

conscious and controlled way shape their career path and experience. There are also studies that present findings on the factors influencing the intention to start up business among students (Banerji et al, 2009). They show that the level of intention concerning starting up business, dependent on or independent (in this case) of the university, is rather low.

Access of young entrepreneurs to finances can be also facilitated through grant financing, debt financing (among which one can distinguish soft loans, microloans and guaranteed loans), equity financing and angel investors. Debt financing are increasingly replacing traditional grant schemes (Curtain 2001). Soft loans generally have zero or low interest rate. The only requirement is to demonstrate commitment, ability to repay the loans and being able to present a business plan. Microloans are particularly interesting for young, as they require limited business experience and generally little collateral. Equity financing is related to the personal savings or family resources. Another way to link young entrepreneurs with sources of financing are angel investors, who provide management advice and important contacts essential for start-ups. (Deeb 2013).

There can be also seen an increasing role of crowd-funding. Instead of traditional investors, crowd-funding campaigns are funded by the general public. Most successful projects receive about 25-40% of their revenue from their first, second and third degree of connections. This could include friends, family, work acquaintances, or anyone that the owner is connected to, including their second and third degree connections. The approach of crowd-funding is attractive to entrepreneurs, because it not only allows raising capital for small businesses, but also serves as a tool for testing marketability. Individuals enjoy the possibility to contribute to the ideas they believe in, even if they can invest only small amounts (Valanciene and Jegeleviciute 2013).

Finally, in concluding the considerations regarding students' sources of income, one cannot leave unnoticed such duties of parents as for instance paying maintenance which will allow students to cover all costs during studying.

The types of students' maintenance solutions during university education described above are not devoid of risk. The risk exists at every moment of submitting documents for financial support to a public institution - the negative decision concerning the application has to be always taken into account. On the other hand, the obstacles in the process of acquiring the source of support, sometimes multiplying in front of the student might stimulate them to start up business, which will be presented in the study on willingness to take risk (Bernat et al, 2014).

## **5 RESEARCH METHODOLOGY**

The subject of research included in the article is the assessment of tendency for risk and intention to start a business in the context of sources of students' acquired income. The study was conducted among 275 students of the University of Szczecin divided into two groups: students of economics and non-economic studies. The period of research was May-June 2014.

The study consisted of two parts. In the first, the survey method was used, the second was conducted with experimental economics methodology. The paper of questionnaire contained socio-demographic questions, which were used to determine the profile of the respondent and the survey questions (5 general and 14 specific questions). The aim of the survey part was to determine the level of the tendency to take risk and to entrepreneurial activities.

According to the aim of the paper, among other things stated willingness to take risk was examined by means of responding to a question concerning the risk connected with starting a business. Thanks to it, thinking to take a risk by respondents was examined. In the study it was assumed that people who stated that starting up business is connected with low risk are the people with high or very high tendency for risk (they are not afraid of risky actions). However, the people who claimed that that starting up business is connected with high or very high risk are the people low tendency for risk. It is based on the fact that in Poland two thirds of companies bankrupt before reaching five-year "maturity". The first year is most critical for newly created firms. According to the data of Polish Central Statistical Office (GUS), before 2007, 62–67% of companies survived this period, the rest being just closed (GUS, 2013). Out of the companies created in years 2007-2011, 71-77% stayed on the market for at least a year. But when a longer-term perspective, i.e. 5 years is taken into consideration, unfortunately less than one third of companies manage to survive. It is significantly less than the EU average where nearly a half of all companies reached the age of 5 years of operating. The second part of the study, based on which the data was obtained and the analysis in the article was performed was based on an economic experiment, which was supposed to indicate the actual tendency for risk (Bernat et al, 2014). The experiment included two issues namely: the willingness to take a risk and usability. It has been designed so that, with higher the risk of choice, the utility of such choice was increasing (the student had a chance to win higher value of prize). There were no time limits at decision making. The experiment did not allow the possibility of a group make decisions. Individual choice options are presented below:

**Choice option 1:**

Stage 1 – 100% guarantee of winning at stage 1. Prize: a candy.

Stage 2 – possibility of playing for a bigger prize. Two options: gamble for a bar of chocolate at lower risk level (50% chance of winning) at a risk of losing the prize from the first stage or a gamble for 2 bars of chocolate with a guaranteed win from the first stage (33,3% chance of winning).

**Choice option 2:**

Stage 1 – 50% chance of winning a bar of chocolate, 50% risk of losing.

Stage 2 – possibility of playing for a bigger prize. Two options: gamble for a small coffee and a bar of chocolate at lower risk level (50% chance of winning), or a gamble for a big coffee and a bar of chocolate at higher risk level (33,3% chance of winning).

**Choice option 3:**

Stage 1 – 33.3% chance of winning a small coffee

Stage 2 - possibility of winning a prize of higher value at a guarantee of receiving a bar of chocolate. Two options: gamble for a medium coffee at lower risk level (50% chance of winning), or a gamble for a small and big coffee at higher risk level (33.3% chance of winning).

The description of the experiment shows that it consisted of two stages - two levels. The first of them, the player has three choice options. The higher the risk in the decision making, the student has the opportunity to win a prize of higher value. Thus, the utility of such choice grew. Each of the participants have the opportunity to finish the game at the first stage or to continue if won in the first stage. However, the choice made in the first stage determined the selection of variants in the second stage. In the event of losing the student received a certificate of participation in the study.

## 6 RESULTS

As outlined in the research methodology its goal became, among other things, to identify the source of income acquired by students. The research showed various sources of students' income, which was represented on Figure 1.

Fig. 1 -Mainsource of income acquired by students.Source: own study.

The data in Figure 1 indicates that the money received from parents was the majority in the students' income. It amounted to 73.8% of the studied population. The incomes from odd jobs and scholarships (34.5% and 28.4%) were of equally significant importance. In the studied group the incomes acquired from full-time job or from other sources played a lesser role. Merely 4.0% of the students obtained incomes from running their own business.

The research shows that the students presented different stated and actual tendency for risk in relation to the acquired income. The students who indicated money from parents as the main source of income, claimed in the survey, that starting business is connected with moderate and average risk (figure 2). Only 14.9% of students claimed that such an action is connected with high and very high risk, and only 5% with low risk. However, the experimental research showed that the analyzed students group expressed in heaping majority high and very high (61.6% of the surveyed) and moderate and average (38.4%) tendency for risk. It was contradictory to the attitude to risk stated in the survey, where moderate and average attitudes dominated (80.2%).

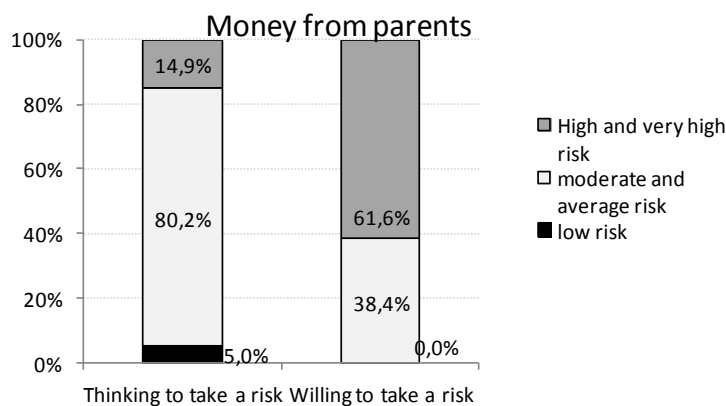

Fig. 2 -Statedand actualtendency for risk among students whose source of income is money from parents.Source: own study.

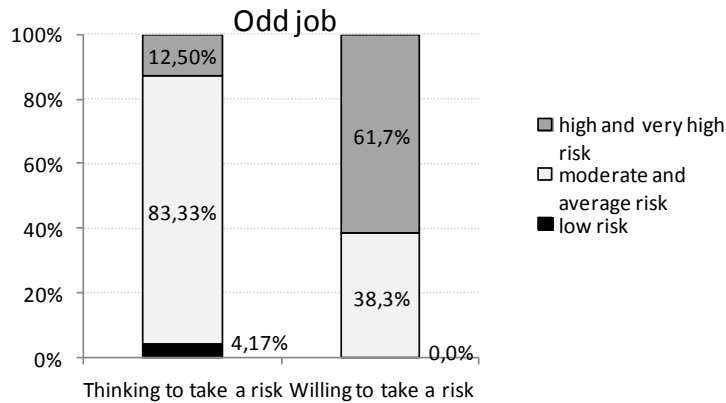

Fig. 3 -Stated and actual tendency for risk among students whose source of income is odd job.  
 Source: own study.

The students who indicated odd job as the main source of income was another studied group. According to the data they were characterized by a similar tendency for risk (stated and actual) as the students whose main source of income was money from parents (figure 3). However, the students whose main source of income during the research was a full-time job (figure 4) were characterized by lower actual tendency for risk than they expressed in the survey. Thus possessing their own job post and the income acquired on this basis resulted in this group avoiding taking risky actions.

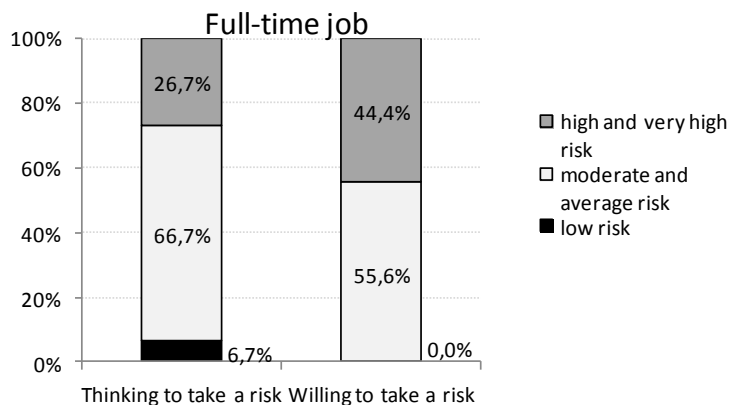

Fig. 4 -Stated and actual tendency for risk among students whose source of income is full-time job. Source: own study.

In the group of students for whom their own company was the main source of income (figure 5) people of moderate and average stated attitude to risk (63.6%) dominated.

The percentage of people who indicated low tendency for risk was relatively high in relation to the other groups, but the people of high and very high tendency for risk were the smallest group. However, the experiment allowed to determine that in practice, this group had lower than stated tendency for moderate and average risk, but the percentage of people of high and very high tendency for taking risk was substantially higher.

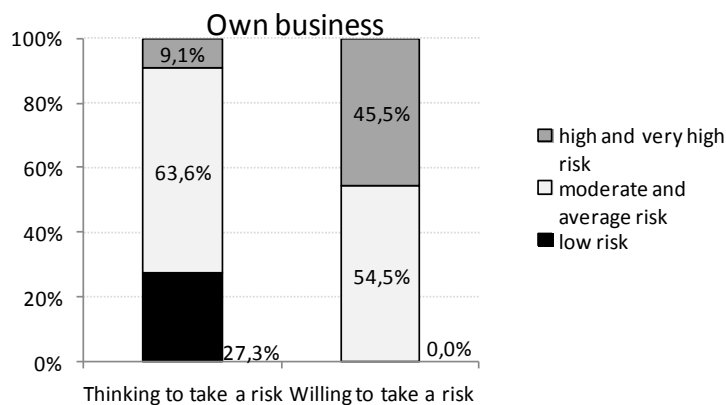

Fig. 5 - (Thinking to take a risk and willing to take a risk among students) Stated and actual tendency for risk among students whose source of income is own company. Source: own study.

The students who indicated scholarship as the main source of income were another studied group (figure 6). According to the survey data, they had moderate and average tendency for risk. Such tendency was shown by 84.6% of the participants. However, high and very high tendency for risk was expressed by only 12.8% of the analyzed students, and small tendency by mere 2.6%. Other conclusions are a result of the experimental data analysis. They show that these proportions are radically different. People of high and very high tendency for risk (62.8%) were the biggest group, whereas nearly half smaller group were the people of moderate and average tendency for risk (37.2%). None of the members of the studied group was of low tendency for risk.

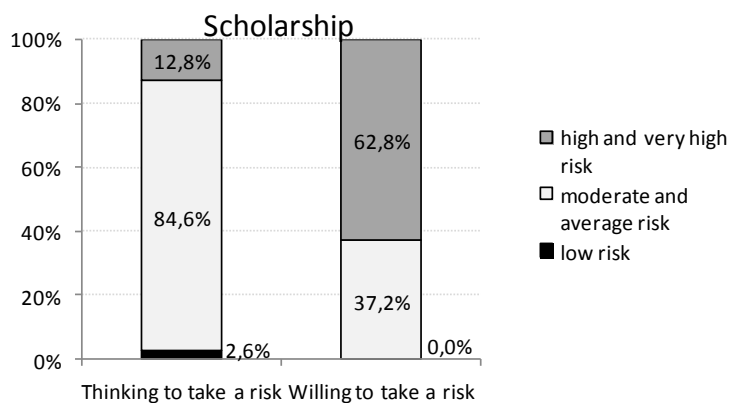

Fig. 6 - Stated and actual tendency for risk among students whose source of income is scholarship. Source: own study.

The students who indicated other sources of income were the last group (figure 7). The survey data allows to state that in vast majority the students from this group had also shown moderate and average tendency for risk (75.0%). 21.9% of students had high and very high tendency for risk, and 3.1% of them – small tendency. Similarly to the previous group, the experimental data showed that the biggest percentage of participants were the people of high and very high tendency for risk (56.3%) and of moderate and average 43.8%. Also nobody in the experimental study was of low tendency for risk.

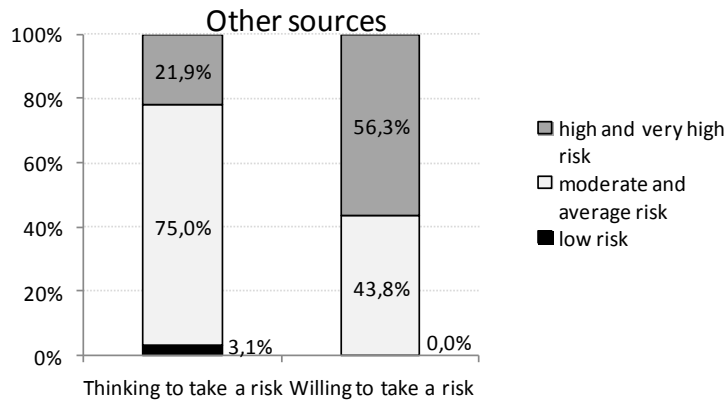

Fig. 7 -Stated and actual tendency for risk among students whose source of income are other sources. Source: own study.

Individual groups of students were also classified according to the participation of high and very high tendency for risk in survey and experimental research (table 1). It was assumed that 1 means the biggest share and 6 the lowest.

Tab. 1 -The classification of individual students groups showing high and very high tendency for risk. Source: own study.

Rank	1	2	3	4	5	6
<b>Thinking to take a risk</b>						
Source of income	Full-time job 26,7%	Other sources 21,9%	Money from parents 14,9%	Scholarship 12,8%	Odd job 12,5%	Own business 9,1%
<b>Willing to take a risk</b>						
Source of income	Scholarship 62,8%	Odd job 61,7%	Money from parents 61,6%	Other sources 56,3%	Own business 45,5%	Full-time job 44,4%

The conducted research showed that there are significant discrepancies for all students groups, concerning stated and actual tendency for risk. It also influences the classification of individual students groups according to, for instance, high and very high tendency for risk. The biggest share within the stated risk was observed among the people getting their income from full-time job (26.7%) and other sources (21.9%), whereas the lowest, nearly threefold lower, among the people having income from their own company(9.1%). However, within the actual risk, the biggest shares occurred among the people acquiring income from scholarship (62.8%), odd job (61.7%) and from parents (61.6%). The lowest shares, in turn, occurred in case of people acquiring income from their own business and full-time work. The differentiation between stated and actual tendency for risk causes big changes in the rank of individual group (the students who live on money from parents are an exception). By way of illustration, people who have full-time job, were highest ranked among all groups with stated high tendency for risk, whereas lowest ranked with actual tendency for risk.

## 7 CONCLUSIONS

The studies concerning entrepreneurial attitudes and tendency for risk are an important contribution to knowing the motivations of decision making concerning starting up business. Certainty or uncertainty of acquiring own incomes together with their influence on making risky decisions is one of the elements of this system. In that sense the studies presented in this paper were undertaken. Their **outcomes partially confirm the hypothesis**, that the ease of acquiring incomes by students facilitates passive entrepreneurial attitudes. Therefore, it confirms the considerations presented in the theoretical part regarding taking up work by students – where taking up work during studies (and thus additional risk) is one of the elements shaping entrepreneurship. It is also consistent with the aforementioned outcomes of the research activities concerning risk as a determinant of decision making and simultaneously individual entrepreneurship. However, the second part of the hypothesis that the ease of acquiring incomes by students facilitates limiting the risk taking. The conducted research point out big discrepancies between stated and actual tendency for risk. It is interesting, since such big differences may prove low awareness of the problem or lack of skill to assess risk subjectively.

The conducted data analysis together with the conclusions formulated on its basis, obviously need further research. It will allow their further verification. The authors of this paper express hope that it will be the beginning of further studies in this field.

## **THE ANALYSIS OF DEPENDENCE FDI FLOWS ON THE SIZE OF CORPORATE INCOME TAX RATES IN EU COUNTRIES**

*Beáta Blechová*

### **Abstract**

As part of international investment flows, foreign direct investment (FDI) has gained much attention by researchers on globalization and tax competition. The use of tax incentives as a means to attract FDI was analyzed in a situation where the removal of barriers to international investment led countries to compete for mobile capital. Currently, there is a relatively strong empirical support for the view that FDI flows respond to tax rates. The interest in the issue of tax competition within the EU has increased in the context of EU enlargement. Considering the relatively low tax rates in the new EU member states, the political debate in Europe focuses also on the effect of taxes on FDI flows. It resulted in some of the old member countries the raising demand for tax harmonization. However, how the lower tax rates in new member countries influence the FDI flows within the EU it is still not entirely clear. In fact, the empirical studies focused on this issue provide different results, what casts doubt the fears of the old member countries from the growth of tax competition. This article therefore aims at analyzing how FDI in the EU are affected by corporate tax rates. For this purpose, it compares the evolution of FDI in the EU in the period among 2004 - 2012, with the development of statutory and effective corporate income tax rates. The dependency ratio of FDI on the tax rates is here determined using the comparative and correlation analysis. Based on the results of this analysis is then assessed the significance of the corporate income tax rates impact on the amount of FDI in the EU.

*Keywords: foreign direct investment, statutory corporate income tax rates, effective corporate income tax rate, macro-backward looking methods, tax competition, comparative analysis, correlation analysis.*

## **1 INTRODUCTION**

In general, the investments are an important factor of economic growth in any country. FDI reflects the objective of obtaining a lasting interest by a resident entity in one economy (direct investor) in an entity resident in an economy other than that of the investor (direct investment enterprise). The lasting interest implies the existence of a long-term relationship between the direct investor and also the enterprise and a significant degree of influence on the management of the enterprise. Direct investment involves both the initial transaction between the two entities and all subsequent capital transactions between them and among affiliated enterprises, both incorporated and unincorporated.

A foreign direct investor is an individual, an incorporated or unincorporated public or private enterprise, a government, a group of related individuals, or a group of related incorporated and/or unincorporated enterprises which has a direct investment enterprise, that is an incorporated enterprise (a subsidiary or associate company), or an unincorporated enterprise (branch) operating in a country other than the country or countries of residence of the foreign direct investor or investors. OECD recommends that a direct investment enterprise be defined as an incorporated or unincorporated enterprise in which a foreign investor owns 10% or more

of the ordinary shares or voting power of an incorporated enterprise or the equivalent of an unincorporated enterprise.

FDI plays an important role especially in developing countries and in countries in transition from centrally planned economies to market-based economies. As reported (Kubicova, 2013) in addition to capital and investment inflows, FDI also brings other important benefits, including, among others, spillover effects, the import of new technology, know-how, training of the host country workforce, networking with home country producers who supply products to them, and job creation. Due to the great importance of FDI for economies, the politicians and researchers endeavour to identify, which factors determine FDI inflows to countries.

FDI are of increasing importance also in the EU. FDI flows among the old EU states (EU15) have substantially increased, but also investments into the new member states (EU13) have significantly increased. Recently, the EU13 have also started to invest abroad. Building on the efforts of countries to compete for mobile capital through removing barriers to international investment is therefore also analyzed the use of tax incentives as a means to attract FDI.

The evaluation of the importance of taxes as a determinant for FDI has changed markedly over time. So, e.g. (Markusen 1995) in his exploration of motives, which act on multinational firms to invest abroad concluded, that here is little support for the idea, that risk diversification or tax avoidance are important motives for direct foreign investment. Meanwhile, following the extensive theoretical research on tax competition for internationally mobile capital has appeared a number of empirical studies, which almost unanimously concluded that high corporate income tax rates (CITR) have a significantly negative effect on the probability of the FDI successful attracting to the stated country. Several of the empirical contributions have explored the factors influencing the FDI outward and inward in EU (see, e.g. Feld & Heckemeyer, 2009).

However, what impact the lower CITR on FDI in the EU is not yet clear. While for example Hartman (1984) reports significant negative impact of CITR on FDI, Wheeler and Moody (1992), among others, found no significant effect of CITR on FDI, and Swenson (1994) even reports its positive impact. The different results of lower CITR effect in the EU13 countries, contained in various empirical studies, thus cast doubt on fears of the EU15 countries from increasing tax competition. Also the theoretical development of the traditional tax literature has pointed out on other factors, which are equally important to attracting FDI. In particular, as suggested for example (Baldwin & Krugman, 2004), the existence of agglomeration economies may tend to “lock in” firms and capital in certain regions which, in turn, enables countries that benefit from these agglomeration economies to retain high taxes.

The increasing political interest about the connection between the amount of CITR and the results of FDI is also influenced by the relatively high unemployment in Europe, which the government hopes to alleviate by attracting the sufficiently large FDI inflows. Moreover, as stated (Görg and Strobl 2001), it is widely believed that FDI inflows into a country have positive productivity spillovers on domestic firms, and this proposition is generally supported by the existing econometric evidences.

Taken together these presumably positive effects of FDI are able to explain the increasing willingness of potential host countries to grant tax breaks or outright subsidies to the multinational firms that open up a new plant in their jurisdiction. However, at the same time there are increasing concerns both among academics and policymakers that multinational firms will illegally avoid taxes through strategic tax planning and profit shifting to low-tax countries (Blechová, Janoušková, Sobotovičová 2013).

Despite the continuing political interest in the usefulness of tax competition and tax coordination or even tax harmonization, as well as the amount of published theoretical analyzes in this area, the impact of CITR differences on the multinationals' decisions is analyzed still insufficiently. So the question, of whether and when is the tax competition in the area of the CITR harmful, has not yet been unambiguously answered.

## **2 METHODOLOGY**

The main objective of this paper is to examine whether CITR play a statistically significant role in attracting FDI into the old and new EU Member States. At first there is done a comparative analysis of the evolution of FDI between countries within the EU and also the development of both statutory (SCITR) and effective corporate income tax rate (ECITR) in these countries.

The advantage of the SCITR is that these data are readily available, both over time and across countries. However, SCITR does not include the effects of different specifics of national tax laws, especially methods for determining the tax base and are therefore very incomplete measure of tax incentives, faced with multinational companies. More preferred tax rates are therefore ECITR, which takes into account differences between the theoretical concept of net economic gains and taxable income that is actually taxed at companies under the tax law in a given country. In the presence of special tax breaks, accelerated depreciation schemes and similar tax incentives, taxable profits may be substantially lower than pure economic profits, leading to diverging measures for SCITR on the one hand and ECITR on the other.

The effective tax rate can be divided into three categories, according to the method used for their determination, i.e. macro backward looking, micro backward looking and micro forward looking methods. In this work they are used the ECITR set by one of the macro looking methods, namely as a percentage of total annual revenues of corporate income tax in a given country to its GDP.

Further to comparative analysis of the FDI flows and CITR evolution, there is then used a method of correlation analysis to verify the veracity of the hypothesis that between the evolution of FDI flows and evolution of CITR there is a direct linear relation.

In the final part of the work is then to carried out an assessment of results of performed analyzes and using the method of deduction are here derived conclusions about the validity of this hypothesis.

## **3 COMPARATIVE ANALYSIS OF FDI FLOWS AND CITR IN THE EU COUNTRIES AMONG 2004-2012**

### **3.1 The analysis of FDI flows**

The data taken from the Eurostat materials contained the absolute values of inflows and outflows of FDI in mil. euro, the ratios of FDI shares to GDP, and the values of the statutory and effective CITR across 28 EU countries in years 2004 - 2012. Due to the vast extent of the basic data taken over, there are presented here only the aggregate or average values in the individual EU Member States for the reporting period.

Table no. 1 (see Annexes) contains the aggregated data on inflows and outflows of FDI in million of euro across 28 states of the EU in the monitored period, including their differences and share. The table shows that the FDI inflow was greater than FDI outflow in 18 EU countries in the monitored period. It occurs in all EU13 countries and in 5 of EU15 countries, namely in Belgium, Greece, Portugal, Sweden and the UK. The largest percentage ratio

between the total inflow and outflow of FDI in the monitored period show Romania (5216%), Bulgaria (3739%), Croatia (2974%), Latvia (1312%) and Slovenia (1175%). On the contrary, the smallest ratio exhibits the Netherlands (78%), France (69%), Italy (49%), Denmark (45%) and Germany (39%). The ratio of total inflows and outflows of FDI is greater than the median (its value is 213%) in 14 countries, and it concerns all EU13 countries and moreover Greece from the EU15 countries. All other EU15 countries show the value of this ratio lower than the median. Czech Republic occupies 7th place with a value of 537%. The average value amounted 1357% for EU13 countries and 106% for EU15 countries.

It is also interesting the comparison of the situation in individual EU member countries by the average value of the ratio  $FDI_{infl.}/GDP$  and  $FDI_{outfl.}/GDP$  presented in Table no. 2. The highest value of the ratio  $FDI_{infl.}/GDP$  shows Luxembourg (387.33), which is about two orders of magnitude larger than at most of other Member States. The next highest values of this ratio show Belgium (14.32), Bulgaria (12.92), Malta (9.78) and Estonia (9.47). The smallest values are then reported by Denmark (1.59), Germany (1.08), Italy (0.96), Greece (0.80) and Czech Republic (0.68). For the 14 member states, the value of this ratio is greater than the median value, which amounts to 3.75. This concerns 9 EU13 countries and 5 EU15 countries (Luxembourg, Belgium, Ireland, Netherlands and United Kingdom). The value lower than median show the 14 countries, including 4 countries from the EU13 group (Lithuania, Poland, Slovenia and the Czech Republic), and 10 countries from the EU15 group. The average value for EU13 countries amounts to 5.50, and for EU15 countries then 28.93, which is significantly influenced by Luxembourg. After its exclusion the average ratio for EU15 countries would be amounted to only 3.38, suggesting a greater FDI inflow into the EU13 countries from the EU15 countries than vice versa.

When considering the ranking of EU countries from the average value of the ratio  $FDI_{outfl.}/GDP$  during the reporting period, then the situation is as follows. The highest values show Luxembourg (400.16 - which is again 2 to 3 orders of magnitude greater than in other EU countries), Belgium (11.35), Ireland (7.76), the Netherlands (7.61) and Sweden (6.34). On the contrary the lowest values occur in Latvia (0.59), Slovakia (0.58), Bulgaria (0.48), Croatia (0.44) and Romania (0.05). Czech Republic occupies the 23rd position with a value of 0.70. Due to the median value which amounts to 2.54, the half of EU countries shows the value of this ratio greater than the median, wherein 11 countries of which are from the EU15 group and 3 countries are from EU13 group (Cyprus, Estonia and Hungary). Values lower than the median shows the remaining 10 countries from the EU13 group and 4 countries from the EU15 group (Germany, Finland, Italy, Portugal and Greece). Germany's inclusion in this group is somewhat surprising. The average value of this indicator is 1.39 for EU13 countries and 30.9 for EU15 countries. After Luxembourg excluding is then just 4.52. The results thus confirm that the FDI outflow from the EU15 to EU13 countries was greater than in the opposite direction in the monitored period.

Extremely high values of both these ratios for Luxemburg are influenced by the fact that up to 340 multinational companies entered into a secret agreement with Luxembourg in order to pay the less taxes. These include e.g. such companies as Apple, Amazon, Ikea, Pepsi or Axa. Informed about it the European media, which refer to the documents of the International Association of Investigative Journalists (ICIJ), based in Washington. Luxembourg agreements from 2002 to 2010 represented by ICIJ the loss of billions of euro. According to the journalists that proves, that large companies are taking advantage of the looser tax laws in Luxembourg to the transfers of their profits into this European country. This is due to the fact that their profits are there not at all or only very little taxed, although the official SCITR in Luxembourg ranged from 30.4% to 28.8% during this period. As reported by the important European media, Luxembourg retains its tax treaty in secret, shall not divulge it to their

European partners, although knows from these international companies, that their strategy is to avoid taxes. This affects the massive inflow of profitable capital into Luxembourg from abroad, including EU countries. In Luxembourg, the capital is taxed only minimally and is then used to re-invest abroad, including again EU countries. Therefore the FDI outflow from Luxembourg is also much higher than in other EU countries. The inclusion of Luxembourg to the comparative analysis of FDI flows in the EU countries therefore causes a distortion of the actual conditions within the EU.

### **3.2 The analysis of CITR data**

As regards the CITR, the average values of these indicators in the EU countries during the reporting period are presented also in Table no. 2 in the Annexes.

These data indicate that the highest average values of SCITR for the reporting period show Malta (35.00%), France (34.77%), Italy (34.02%), Belgium (34.00%) and Denmark (33.93%). On the contrary the lowest values show Lithuania (13.33%), Cyprus (10.56%), Latvia (15.00%), Ireland (12.50%) and Bulgaria (12.17%). Czech Republic and Germany shared the 16th place with (22.22%). The median value, which amounted 26.09%, there exceeded half the EU countries, including 12 from the EU15 group and 2 from the EU13 group (Malta and Estonia). The second half of the EU countries, which showed values lower than the median, involved 11 countries from the EU13 group and 3 countries from the EU15 group (Austria, Germany and Ireland). The average value of this indicator amounted then 19.62% for the EU13 countries and 28.33% for EU15 countries. These facts confirm the existence of lower SCITR values in most EU13 countries compared to the values of this tax rates in the EU15.

In the reporting period there was a decline of SCITR at 17 EU states, while in 6 EU states this decline was fluctuating. The largest decline occurred in Bulgaria and the Netherlands (-9.5 percentage points) and the Czech Republic, Austria and Romania (-9 p.p.). At the 7 states the value of SCITR was unchanged during the reporting period (Belgium, Ireland, Croatia, Latvia, Malta, Poland and Slovakia). At Lithuania this value has changed, but at the end of the reporting period it was as large as at the beginning. On the contrary at 3 countries the SCITR has increased, namely in Portugal (+4 p.p.), Hungary (+3 p.p.) and France (+0.7 p.p.). Maximum values in 2012 showed France (36.1%), Belgium (34.0%), Portugal (31.5%), Italy (31.4%) and Germany (30.2%), the lowest value then the Czech Republic (19.0%), Lithuania (15.0%), Ireland (12.5%), Bulgaria and Cyprus (10%).

In the case of ECITR the situation developed as follows. The highest average value of this tax rate for the reporting period occurred in Hungary (6.58%), Cyprus (5.97%), Luxembourg (5.48%), Malta (5.36%) and the Czech Republic (3.98%), the smallest value then in Lithuania (1.89%), Estonia and France (1.51%), Spain (0.79%) and Croatia (0.50%). A value greater than the median, which amounted to 2.76%, showed half of the EU countries, including 9 from EU15 group and 5 from EU13 group (Hungary, Cyprus, Malta, the Czech Republic and Romania). A value lower than the median then showed 8 countries from EU13 group, and 6 from EU15 group (Italy, Germany, Greece, Austria, France and Spain). The average for the EU13 group was 3.09% and was higher than in EU15 group, where it reached the value of 2.63%. Their ratio was therefore opposite to that in the case SCITR. The above mentioned data indicate a much smaller differences in the level of ECITR values between old and new EU Member States, than in the case of SCITR.

In the reporting period, the ECITR value decreased in 19 Member States, in 4 of them did not change (Belgium, Croatia, Austria and Sweden) and in 5 states has increased (Germany, France, Cyprus, Malta and the UK). The maximum of ECITR value change between the beginning and the end of the reporting period showed Malta (+2.7 p.p.), Cyprus (+2.4 p.p.),

Greece (-1.9 p.p.), Ireland and Finland (-1.3 p.p.). At the end of the reporting period, i.e. in 2012, the highest values of ECITR reached Malta and Cyprus (6.3%), Hungary (5.4%), Luxembourg (5.3%) and the Czech Republic (3.3%), the lowest values then Slovenia and Lithuania (1.3%), Greece (1.1%), Spain (0.7%) and Croatia (0.4%).

#### **4 CORRELATION ANALYSIS OF THE DEPENDENCE BETWEEN FDI FLOWS AND THE SIZE OF CITR IN THE EU**

Already a mere optical comparison of the FDI flows development in the period among 2004 - 2012 with the development of CITR across EU member countries in this period points to very little direct dependence between those random variables. For more exact assessment of whether there is a certain degree of linear dependence between the random variables, there was used here a statistical method of correlation analysis.

In this work it is analyzed the degree of correlation between selected files of random variables X and Y in individual EU Member States. X files are represented by selected files of SCITR and ECITR, which relating to the years 2004 - 2012 (i.e. the parameter  $n = 9$ ). Files Y then represent the temporally corresponding selected file of random variables representing the absolute value of the inflows and outflows of FDI, and also proportions these inflows and outflows to GDP. The results of calculations of selected correlation coefficients  $r$  at the individual EU countries are listed in Table no. 3. To determine whether the values of these coefficients indicate the existence of a linear dependence between researched files of random variables X and Y, these values were compared with the critical value of  $r_p$ , which was found in the tables for the parameter  $\nu = n - 2 = 9 - 2 = 7$  and for selected significance level of  $p = 0.05$ . Critical value in this case is  $r_p = 0.6664$ . In the case that the calculated selective correlation coefficient  $r$  satisfies the condition  $|r| > 0.6664$  we can consider the analyzed dependence between selected files of random variables X and Y as linear with the probability  $P = 100(1 - 0.05) = 95\%$ .

The dependence between data files containing data on FDI inflows and data files containing information about CITR should be inversely proportional, i.e. the selective correlation coefficient  $r$  should be negative, because with the rising tax rates in the home country should inflow of FDI into this country to fall. On the contrary, in the case of depending of data file containing information about FDI outflow, and of data file containing information about CITR should be a direct proportion, i.e. the correlation coefficient  $r$  should be positive, because with the rising tax rates in the home country should inflow of FDI into this country also growth.

From Table no. 3 then it follows that dependence of the data file  $FDI_{infl.}$  on the data file SCITR does not show a linear relationship at the any EU Member State. Similarly it is with depending of data file  $FDI_{infl.}/GDP$  on the data file SCITR. For datasets  $FDI_{outfl.}$ , and SCITR can infer on the linear relationship between them only for Spain ( $r = 0.6857$ ), and for data files  $FDI_{outfl.}/GDP$ , and SCITR, only for Slovenia ( $r = 0.6792$ ).

The situation looks to be better at the depending of data files containing information about FDI flows, and data fail ECITR. In case of the files relating to the data  $FDI_{infl.}$ , it can be assumed a linear dependence only at Ireland ( $r = -0.8268$ ), for the files with the data  $FDI_{outfl.}$  then at the Estonia ( $r = 0.7152$ ), Spain ( $r = 0.7234$ ) Italy ( $r = 0.7242$ ), the Netherlands ( $r = 0.8239$ ), Austria ( $r = 0.9318$ ) and Slovenia ( $r = 0.8227$ ). Similar looks the situation at data files containing information about FDI flows in relation to GDP. For data files containing  $FDI_{infl.}/GDP$  values can be a linear dependence on ECITR considered also only at Ireland ( $r = -0.7025$ ), while for data files containing  $FDI_{outfl.}/GDP$  values it comes into consideration

again in Estonia ( $r = 0.6989$ ), Spain ( $r = 0.7928$ ), Austria ( $r = 0.6967$ ) and Slovenia ( $r = 0.9501$ ), and also in Lithuania ( $r = 0.6967$ ).

If we used a significance level of  $p = 0.01$  to determine the critical value of  $r_p$ , the  $r_p$  value would have been  $r_p = 0.7977$ . In this case the condition  $|r| > r_p$  would be met in only four cases, namely at the depending  $FDI_{infl.}$  on the ECITR in Ireland, at the depending  $FDI_{outfl.}$  on the ECITR in the Netherlands and Austria, and at the depending  $FDI_{outfl.} / GDP$  in Slovenia.

Having the regard to the above information, the linear relationship between FDI flows and SCITR can be completely excluded. The situation seems to be similar at the dependency  $FDI_{infl.}$ , and  $FDI_{infl.} / GDP$  on ECITR. The dependence of the  $FDI_{outfl.}$ , and  $FDI_{outfl.} / GDP$  on ECITR exhibits the linear character for  $p = 0.05$  at the 6 EU countries, and for  $p = 0.01$  only at the 4 EU countries. This is the insufficient number, so that we could consider the determined existence of a linear relationship between the size of FDI flows and the size of the CITR in EU countries to be statistically significant.

In the case when the files of random variables X or Y comprises the elements of the same value, i.e. that  $x_i = \text{const.}$  or  $y_i = \text{const.}$ , then the value of the denominator in the formula for calculating of the selective correlation coefficient  $r$  equals zero. In this case this factor can not be calculated and in the appropriate cell of Table no. 2 is the note # DIV / 0!

## **5 CONCLUSION**

FDI plays an important role in the economy of each state. They contribute primarily to an increase in GDP, employment, for attracting respectively invocation secondary investments, access to advanced technologies and to developed managerial experience, to greater access on the developed markets and to the increase of the state budget revenues from taxing profits generated by them. Therefore the states that do not have sufficient volume of own investments, endeavor to attract investment from abroad. For this purpose, they are trying to create more favorable conditions for business of potential foreign investors in their countries than they have in home countries. And because the main goal of business is the making a profit, the host states trying to create more favorable conditions for it. An important factor affecting the amount of corporations profit is the rate of its taxation. Therefore, the host states are trying to reduce the tax rate compared to the home countries of potential foreign investors, which can cause origin of tax competition between states.

The rate of corporate profits taxation can be assessed in different ways. Most often they are used for this purpose SCITR because they are readily ascertainable. Therefore, the tax competition focuses mostly on their reducing. We can observe this even in the EU, where the average value of this tax indicator for the period 2004 - 2012 amounted to 19.62% in the EU13 new Member States, while in the old EU15 Member States achieved the value 28,33% (the difference was 8.71 p.p.). The value of this difference between the beginning and the end of the reporting period decreased from 9.9% to 8.4% (in 2004 was the  $\emptyset$  SCITR in the EU13 countries 21.5%, and in the EU15 countries 31.4%, in 2012 these values amounted to 19.0% and 27.4%). These lower values of SCITR in the EU13 countries, compared to EU15 countries, correspond to a significant difference in the percentage ratio of the FDI inflow and outflow in these countries within the EU throughout the reporting period, when at the EU13 countries it amounted to 1357%, whereas at the EU15 countries only 106%. The EU15 countries consider this competition at SCITR as harmful, and therefore are making efforts for the introduction of its harmonization within the EU, similarly as it was performed at VAT rates.

However, SCITR expresses only the degree of theoretical corporation tax burden in the respective country. The effective tax burden may be substantially less, because next SCITR it is influenced by other factors. They are mainly the rules for determining the amount of the tax base, contained in tax legislation, and various tax relief provided by states to foreign investors in order to attract them. These tax relief measures can include:

- Tax holidays
- Investment deductions and investment offsetting
- Disposable depreciation, time freely chosen amortization or faster depreciation
- Repayment of customs duties
- Lower income tax rates than SCITR for foreign investment
- The mutual links between the taxation of income in the host and home country, advantageous for foreign investors

In addition to these tax factors, the investors make decisions about the direction of their foreign investments also according to other non-tax factors such as: qualification and wage levels of staff, level of infrastructure, market size and purchasing power of the population in the country, guarantee against a possible expropriation, liberal regulation of national and foreign currencies exchange, consent with international arbitration of the disputable cases or state financial aid in the form of preferential loans, of the share in capital in newly founded companies or of direct financial subsidies to foreign investors.

From the above reasons it follows, that the mere level of SCITR in individual EU countries can only minimally influence the volume of FDI flows in these countries. It unambiguously demonstrates the correlation analysis presented here, the results of which showed, that there is no linear dependence between volumes of FDI flows and the size of SCITR in individual countries, even at a significance level of  $p = 0.05$ . Graphical form of evolution of these indicators in the monitored period optically does not reflect nor their other than a continuous linear relationship.

The actual amount of the tax burden better express the ECITR than SCITR. In case of the ECITR, which were determined by some of the macro or micro backward looking methods, it is influenced by the fact, that for the expression of the corporations tax burden they use the values of overall actually paid corporate income tax, either at the macro (i.e. national) level or at the micro (i.e. corporate) level. In this work was analyzed the dependence of FDI flows on ECITR, where the ECITR values were determined using macro backward looking method, namely as a proportion of total revenue from corporate income taxes to GDP. The average value thus determined ECITR in the group of member states EU13 during the reporting period amounted to 3.09%, which was higher than in EU15 group, where amounted to 2.83%. Their ratio was therefore opposite to that in case of SCITR, which does not confirm the claim that lower SCITR in countries EU13, compared to the EU15 countries, reduce the corporation tax burden in the EU13 countries, and thus causes the harmful tax competition between old and new EU Member States.

Correlation analysis aimed at finding out, whether exist a linear dependence between the size of FDI flows and the ECITR values showed, that at the chosen significance level of  $p = 0.01$ , such dependence exist only in four cases, namely: at the  $FDI_{infl.}$  dependency on the ECITR in Ireland, at the  $FDI_{outfl.}$  dependency on ECITR in the Netherlands and Austria, and at the  $FDI_{outfl.} / GDP$  dependency on ECITR in Slovenia. On the basis of this result a linear relationship between the values of FDI flows and the ECITR values in EU countries can not be considered as statistically significant. Similarly to the case of SCITR here also applies that optical assessment of the graphical representation of development FDI flows, and of the

ECITR values development in the reporting period does not reflect nor the non-linear dependence of these random variables.

So it can be concluded, that the analysis of the dependency FDI flows on the size of CIRT in the EU countries, does not confirm the hypothesis laid down at the beginning of this article, that between evolution of FDI flows and CIRT exist a linear relationship. But it is also necessary to state, that the results of this analysis could be to some extent influenced by effects of the global financial and economic crisis in 2008.

## **CUSTOMER AUDIT AS AN IMPORTANT TOOL STIMULATING COMPANY GROWTH**

*Petr Briš, Petr Klímek*

### **Abstract**

Customer audit is being used for screening the supplier if he is able continuously supply products or services according to our needs. Such audits shall be helpful in permanent improvement of supplier-customer relationship and to simplify new business deals. Customer audit added value shall be viewed in clarification of all specified demands and expectations leading to the continuous product improvements for both sides. But in reality it is not often the case, especially when customer audit is performed formally, without any conception or by outsourcing. This paper is analyzing the results of quantitative research in customer audits sector related to Czech corporations and steps are proposed which can lead to the valuable businesses management.

*Keywords: Audit, Customer Audit, Quality Control, Quality Management, Process Quality, Customer – Supplier Relationship.*

JEL Classification: M20

### **1 INTRODUCTION**

Audits are very important tools leading to development and growth of a company. This article focuses mainly on a customer audit. From a previous research it was discovered that these audits are conducted merely formally. Auditors often concentrate only on performance standards set by ISO 9001 norm. However, if audits are being done to add value and to stimulate growth and beneficial customer-supplier relationships, they should be oriented on other important aspects like work safety, corporate culture, financial health, CSR, level of innovation, environmental impact, stakeholder satisfaction etc. The results are known from external audits of other management areas, for example from environmental management indicate that for improving environmental quality is needed to put forth the greater efforts in environmental audits (Huang et al., 2014). It was also found that the empirical tests concern the combined effect of external audit of quality and institutional property has effect on earnings management (Kouaib & Jarboui, 2014).

### **2 THEORETICAL BACKGROUN)D**

In current business environment a vast number of companies ranging from small to large ones use a well-established quality management system (QMS) certified under ISO 9000 series. QMS help businesses sustain a stable quality level by checking primary and support processes. The ISO 9000 family identifies eight quality principles leading to better performance. These are:

- customer focus,
- leadership,
- involvement of people,
- process approach,

- system approach,
- continuous improvement,
- factual approach to decision making,
- beneficial supplier relationships.

As Khan (2001) says the cycle of accreditation to ISO 9000 involves a review of system documentation, a physical audit, an audit report review, and, if successful, periodic surveillance audits. A company claiming to have a good quality system must be able to prove it by systematic quality checks, reviews or audits.

The international audit standard ISO 19011 defines a quality audit as an evidence gathering process which assesses whether set criteria are being met. This standard also differentiates three types of audits:

- First party audits which are internal audits used by companies to review themselves.
- Second party audits which are external audits usually performed by external auditors, companies or customers.
- Third party audits are done by independent regulatory bodies.

In general, ISO 9000 quality audits assure that:

- Processes are stable and in accordance with a documentation.
- Quality system is integrated into the company.
- Products or services are suitable for use.
- Rules, regulations and laws are obeyed.
- Information is not biased or misrepresented.
- Customers are satisfied.

However, when the ISO 9001 certificate is awarded a significant number of businesses fail to go beyond the scope of this certificate. Although many researches conducted before 2000 (Bart, 1994; Pfeiffer 1996) showed that companies certified with ISO 9001 improved their efficiency and quality, researches done after 2000 argued that these standards do not guarantee business success and satisfaction of all stakeholders (Wilson, 2000). In addition, in first years after certification, the impact of ISO 9000 is greater and within five years it decreases if no further targets are set (Ismail & Hashmi, 1999).

The perception of ISO 9000 series reflects audits as well. Very often audits are performed only in compliance with set standards of ISO 9000. Auditors usually simply report whether the audit findings agree with the audit criteria or not. According to Pivka (2004) ISO 9000 requirements do not ensure businesses a better quality of products, a greater competitiveness, customer satisfaction or business goals realization. He points out that it is necessary to extend audits to all areas that effect companies. Focusing only on ISO 9000 standards does not stimulate growth and innovation but it can drain resources.

Audits that search for improvements are known as audits that add value (Alič & Rusjan, 2009). In order to serve as a managerial tool helping with further decision making process and growth, auditors should investigate areas of the business that cover wider range of processes. In other terms, companies' quality objectives (set by ISO 9000) should relate to the strategic objectives set by managers, and therefore such audits should investigate e.g. work safety, corporate culture, financial health, level of innovation, environmental impact, stakeholder

satisfaction etc. If we state that audits performed within ISO 9000 limits are formal, further inspections can then be called informal audits.

An example, supporting the claim that audits should be perceived as a management tool for improvements of standardized quality management systems (Alič & Rusjan, 2009), can be seen in a performed Slovenian survey in which 89.9% of questioned companies agreed that internal audits contribute to further business development and grow (Piskar, 2003).

Our research is mainly focused on a specific type of audit known as customer audit. This audit is designed for companies that want to control their suppliers and want to ensure that supplied products or services are in accordance with their input. These audits help to improve existing customer-supplier relationships, or facilitate new ones, between all stakeholders. Again all previously mentioned statements regarding ISO 9000 apply to this type of audit as well (Gong, 2004). To have the best use of customer audits, managers should outreach the norms, have clear communication channel, moreover they need to help customer audit to be a value-adding activity.

A case study by Nenadal (2006) shows how DOMOV s.r.o. company dealt with customer audit of its suppliers. Managers created a list of criteria by which they assess suppliers. These are:

- strategic management,
- environment,
- processes,
- quality assurance,
- logistics,
- employees satisfaction,
- financial health and stability,
- product innovation,
- resources,
- customer – supplier relationship.

They decided not to perform customer audits formally in accordance with ISO 9000 but to go beyond the formality and examine other important factors with DOMOV values.

According to Bris and Pavlova (2013) customer audit:

- Leads to quality assurance of purchased goods.
- Provides a guarantee of partner's reliability.
- Is a starting point for continuous improvement and optimization of supplies.

Goals of customer audits:

- To foster mutual trust between customers and suppliers.
- To develop and sustain clear communication channels.
- To improve and endure a long-lasting partnership.

In principle it would be natural to expect that second party audit results would correlate more closely with achieved quality performance. This is because the customer would have access to

the supplier's quality data and first hand experience of the problems that the supplier had experienced in the supply of their product. This 'insider knowledge' should provide key clues for the auditor to focus on during the audit.

Case studies demonstrated that the second and third party assessment approach is not a reliable indicator of a supplier's quality performance and therefore it can be concluded that an alternative approach to supplier evaluation is required, replacing the need for a third party certification standard to approve the quality capability of suppliers.

The literature review and case studies were described earlier, indicated that final results of traditional audit processes were not effective at determining the quality capability of a supplier organisation and hence another method had to be established. The literature review suggested that there were other certification schemes that had developed from the basis of ISO 9001 and had introduced several enhancements to take account of some of the problems identified with second and third party certification. These are:

- Establishing minimum performance standards.
- Producing transparency for key metrics through public reporting.
- Engaging key stakeholders to verify the organisation's performance /claims.

Therefore, these would be considered in the development of a supplier evaluation process. The supplier evaluation process is designed to:

- Evaluate the quality performance of new / unknown suppliers to the organisation using minimum performance standards
- Enable the comparison of performance data to that already available for the organisation's existing approved suppliers
- To be verified without the need for second or third party assessment
- To take into account the specific requirements of different commodity suppliers i. e. It shall utilise a contingency approach to enable the process to be adapted to the specific needs of the supplier group under evaluation. The attention shall concentrate on quality performance evaluation but recognises that the process may benefit from further expansion to include other criteria such as operational, financial and environmental performance indicators (Riggs, 2004).

Based on the theoretical research, one main question was raised:

- Customer audits in the Czech companies are conducted only in formal way.

### **3 METHODOLOGY**

Data were collected during the year 2013. Heterogeneity of respondents was achieved from the geographical perspective, company size (27 companies with less than 50 employees, 53 companies within 50-100 employees and 13 larger companies), 57 Ltd companies, 32 corporations and 4 other legal forms. Data sampling process was not random, though. Convenience sampling was used for part of the sample to gather information from companies with relevant experiences and history. Moreover, 22 companies from 71 valid responses have never undergone customer audit. These companies are therefore omitted from the following analysis. There were 17 small companies (<50 employees) in the omitted list.

Questions were recorder on dichotomous scale. Reliability of question cannot be assessed analytically (e.g., using Cronbach alpha) because of the design of the questionnaire. However,

questionnaire was designed by two experts with several years of business history. We shall therefore consider questions as reasonably reliable and valid.

We have selected test based on Pearson's  $\chi^2$  statistics to test our qualitative data. These tests test difference between empirical data and expected results. If some conditions were not met (such a small number of observation in combination of responses) and asymptotical estimates of p-value would be incorrect, exact Fisher test were used instead. The special case of  $\chi^2$  test of contingency table analysis is one or two sample proportion test when dimension of contingency table is 1 by 2. Results will be described in terms of achieved test statistics and corresponding p-value. We will compare this p-value to usual  $\alpha$  level of 5%, which represents the probability of committing I type mistake.

We consider formal audit as such an audit which is not exceeding scope of general framework, e.g., ISO 9001.

## 4 RESULTS

First question related to formal auditing practices asked whether the auditing process was guided by questions adopted from ISO 9001 standard. Number of positive answers was 54 which represent 76 % of all companies. Confidence interval for true proportion of formally audited companies ranges from 0.64 to 0.85. This brings strong evidence that more than the halves of the companies which undergo customer audit are audited only formally.

To support our claim we analyse relation between questions related to the presence of top managers during customer audits and question which asks whether company usually receive the program of audit in advance (at least two weeks). All companies claim that they receive program in advance, but only 39.4 % of them are asked for the presence of top management during the audit. Confidence interval of this proportion estimate crosses 0.5 (95% CI = 0.282–0.518) so we don't find an evidence for a claim that the presence of top managers is not wanted by majority of customers. Although all respondents received audit plan in advance, only 30.9 of them usually receive self-assessment questionnaire which they are asked to fill in advance (with upper limit of confidence interval of 0.432). On overall, 93 % of companies do confirms that the program was completely met during the audit.

In the next set of questions we compare responses on question which asks whether technical details and specific requirements on goods and service were discussed during consumer audit (hereafter Q1). We assume that audits which are formal will have smaller proportion of positive response on this question. Firstly, we analyse relation of Q1 to answers on question in Table 1, whether audit was guided by question adopted from ISO standards.

Tab. 1 – Contingency table of Related Questions. Source: Own

		Question related to ISO	
		No	Yes
Technical questions (Q1)	No	0	26
	Yes	17	28

Contingency table summarises responses on Q1 and ISO-oriented customer audit (answers in second columns refer to ISO-like oriented audit). Fisher exact test revealed that association between questions is conclusive (p-value < 0.01). The link between ISO oriented audit and audits discussing technical aspects is direct. Reading from the residuals, if there were no

relation between variables we would expect more answers in combination No-No. This table suggests that ISO-related audits tend to be less technical.

In the next Table 2, analysis Q1 was set against question related to Occupational Health and Safety.

Tab. 2 – Contingency table of Related Questions. Source: Own

		Audit concerned by Occupational Health and Safety	
		No	Yes
Technical questions (Q1)	No	5	21
	Yes	12	33

Contingency table does not reveal any tendency in answers. Based on the contingency table in Table 2 we cannot claim that audits oriented on technical question usually do not focus on issues related to Occupational Health and Safety. We have not found any evidence in formal test, too ( $\chi^2 = 0.1753$ , p-value = 0.675).

In this paragraph we will discuss corporate culture and its relations to other questions. First, let's consider relation to formal-like audit style. Corporate culture is an important dimension of company growth not discussed thoroughly in ISO standards. It would be expected that companies which consider customer audits as formal would also answered that auditors were not concerned about the corporate culture. Responses can be read from the Table 3. As contingency test show, there is no statistically significant association found in our data ( $\chi^2 = 0.6106$ , p-value = 0.4346).

Tab. 3 – Contingency table of Related Questions. Source: Own

		Corporate culture was considered	
		No	Yes
ISO guided customer audit	No	6	11
	Yes	27	27

No evidence for association can be read from the contingency table (Table 3). Following the discussion from previous paragraph about the corporate culture, we identify combination of answers on Q1 and corporate culture, too.

Tab. 4 – Contingency table of Related Questions. Source: Own

		Audit was concerned about corporate culture	
		No	Yes
Technical questions (Q1)	No	10	16
	Yes	23	22

Contingency table does not suggest any association between variables as the cell counts are very similar to each other. We cannot claim from Table 4 that during technically oriented

audits corporate culture is discussed in higher or smaller extent than during the non-technically oriented customer audits ( $\chi^2 = 0.6125$ , p-value = 0.4339).

The next set of questions relates to the presence of discussion about financial health. It might be expected that audits during which financial position of the company is discussed is more detailed and informative. From the responses we can read that 46.5 % of respondents have discussed financial position during the audit. Furthermore, we were interested whether customer is also interested in discussing his/her own problems which weakens the strength of relationship between business partners (Table 5).

Tab. 5 – Contingency table of Related Questions. Source: Own

		Customer's interests in our mistakes and demerits.	
		No	Yes
Customer was interested about financial health.	No	16	22
	Yes	12	21

Structure of contingency table does not suggest presence of association between variables. This is confirmed by formal analysis of Table 5 do not reject null hypothesis about non existing association ( $\chi^2 = 0.0626$ , p-value = 0.8024).

One question was designed to gauge interest of customer in helping to the audited company with identification of threats and opportunities to strengthen good prospects of company growth. Company were asked whether they were offered by customers to receive some analysis during the audit (such a SWOT analysis). However only 6 companies responded positively which means that this practice is only rare and we cannot utilise it as an indicator of non-formal audit.

The last question is related to the quality agreement between companies – whether such agreement exists or not. We have combined this answer with finance perspective as in Table 5.

Tab. 6 – Contingency table of Related Questions. Source: Own

		Is quality agreement signed?	
		No	Yes
Customer was interested about financial health.	No	23	15
	Yes	10	23

Combination of answers does not suggest presence of association between customer's interest about financial conditions of audited company and existence of quality agreement in Table 6. Results obtained in Table 6 were tested by Pearson contingency test which find evidence for presence of association ( $\chi^2 = 5.3274$ , p-value = 0.02099). In situations when quality agreement is signed/not signed, customers tend to be more/less cautious about financial conditions of the audited company.

## 5 DISCUSSION AND CONCLUSION

The quality management system of a producing company secures that a product meets the determined quality requirements. The effectiveness of the quality management system and the processes are inspected and corrected on announced audits and other inspecting actions. The good quality management system depends on the actions and the given profession as well. The audit is a systematic checking of an institution which checks the goals, the aptitude and the efficiency of the system. The purpose of the revision made by the customer is to check that the requirements described in contract were granted. On the basis of result of the audit on the field made by the deliverer we take cognizance that if the company can grant a factual order in pursuance of the needs and expectations of the client. According to the high quality expectations of the products the costumer expects a high-toned and excellence product and supply standard from deliverer.

If the corporation is healthy, with highest profit, efficiency, good will and image, it shall form a good corporate strategy as well. Part of such strategy is decisively a partnership with its suppliers. Prerequisite for a positive partnership development is work on its weak and/or strong parts, as they can be recognized by a supplier audit.

Based on questionnaire survey performed within Czech companies it was confirmed, that the approach toward customer audit is often formal and thus not used with its great potential for company performance growth. Many times they concentrate on supplier screening such as the criteria included in system standards only one chance to improve such situation can be the use of self-assessing check lists, which can include other questions than the system standards.

## **DO INVESTORS HERD IN FRONTIER STOCK MARKETS? EMPIRICAL EVIDENCE FROM VIETNAMESE STOCK MARKET**

*Bui Duc Nha, Nguyen Thi Bich Loan, Nguyen Thi Tuyet Nhung*

### **Abstract**

This paper provides further evidence on herd behavior in the Vietnamese stock market – a frontier stock market. By modifying and employing the non-linear regression models proposed by Chang et al. (2000), the study found evidence of strong herd behavior in all industrial sectors, Hochiminh, and Hanoi stock exchange. Besides, we use a modified model to capture any impact of international stock markets on investor behavior in the Vietnamese market. The results show that herd behavior found in all market portfolios are affected by the U.S stock market. Alternatively, events in Hong Kong stock market only have a relatively effect on Hochiminh and Hanoi stock exchange. However, no evidence of herding was reported. Finally, the results strongly suggest that investors tend to herd in both up and down market scenarios.

*Keywords: herd behavior, individual investors, efficient market*

JEL Classification: G11, G14

## **1 INTRODUCTION**

Since initially defined by Christie and Huang (1995), investor herd behavior has received extensive interest from academic research. Herding behavior is simply defined as an investment strategy based on mimicking other investors' actions. From financial perspective, herd behavior can be either irrational or rational. As defined by Christie and Huang (1995), irrational herding is a tendency where investors make their investment choices solely on the actions of the market and irrationally disregard their own beliefs and analytical skills, even when they perceive the market's prediction to be wrong. On the other hand, rational view of herding indicates the scenario where herding is a result of principal-agent problem in which managers replicate the actions of others, completely ignoring their own private information to maintain their reputation in the market (Scharfstein and Stein, 1990; Rajan, 1994). The rational herding may also occur among individual investors when they rationally follow the actions of others to whom they believe may be better informed and their performance hence would not be below the market average (Demirer and Kutan, 2006).

Motivated by such important implications of herd behavior, numerous works have been conducted. However, most of studies examine herding in developed and emerging financial markets, leaving a loophole of herding literature on frontier markets. To our best knowledge, only a study of Chen (2013) provides a full investigation on herding of 26 frontier markets which are classified based on the MSCI Market Classification Framework. The study consistently found evidence of herding in most of the frontier markets. Although successfully giving a broader view of herd behavior in the frontier markets, the study of Chen (2013) is limited in providing further confirmation of herding in industry context, which is a new growing strand of herding literature. So far, there are only three recent papers of Yao and He (2014), Cakan and Blagoyzian (2013), and Derimer et al. (2010) extend their study of herding in industry perspective.

Therefore, in this paper, we again perform herding tests to Vietnamese stock market – a frontier financial market. However, the study is different to the prior works of Chen (2013), Tran and Truong (2011) and Kallinterakis (2007) who solely investigated the existence of herding in Vietnamese stock market. Particularly, our study further focuses on investigating herding evidence on industry (sector). Hence, result of this study expectedly provides additional contribution to the recent literature that examines herd behavior in an industry context. Besides, the study attempt to investigate if developed stock markets such as the U.S and Hong Kong affect investor behavior in Vietnamese stock market.

The remainder of the study is organized as follows. Section two briefly summarizes the literature on the tests of herding behavior. Section three provides the description of the data and testing methodology while empirical findings and discussion are focused in section four. Section five presents a conclusion of paper.

## **2 LITERATURE REVIEW**

Investigations on the existence of herding behavior in the global financial market are numerous but the results are mixed. Christie and Huang (1995) employed the cross-sectional standard deviation of returns to capture herding behavior and found no evidence of herding in US markets as shares' return dispersion increases instead of decreasing during periods of extreme price movement. In a study of Chang et al. (2000), no significant degree of herding was observed in developed financial markets such as US, Hong Kong and Japan. In contrast, Nofsinger and Sias (1999) reported that high level of herding behavior actually exists in the US market, particularly among institutional investors. Contributed to the positive evidence of herding behavior, Iihara et al. (2001) concluded that Japanese individual and institutional investors are more likely to herd, but foreign investors' investment decisions were made based on available information in the market. Especially, in a recent study of Chiang et al. (2010), daily data from May 25, 1988 to April 24, 2009 was employed and significant evidence of herding was found in many markets including Australia, France, Germany, Hong Kong, Japan, the UK, Argentina, Brazil, Chile, Mexico and other Asian markets such as China, South Korea, Taiwan, Indonesia, Malaysia, Singapore and Thailand. The results challenge the earlier literature which shows no herding in those developed markets.

Empirical researches investigated in emerging markets report higher level of herding, especially in Asian markets. An explanation for this observation is laid on the market inefficiencies in these countries which were characterized by weak market regulation, high degree of government intervention, less-educated investors and lower requirements regarding listed companies' information disclosure. Besides the finding of Chiang et al. (2010) mentioned above, there were other studies also found herding behavior in emerging markets. Chang et al. (2000) strongly found existence of herding in South Korea and Taiwan. They observed that there are incomplete information disclosure and greater impact of macroeconomic information on investment decision-making. As a result, investors have tendency to herd around the market consensus. Chianget al. (2010) used a least squares method to investigate the herding behavior in Chinese stock market and found that both Shanghai and Shenzhen A-share market display herding behavior, but B-share investors do not show such behavior. They explain that B-share investors, mostly composed of foreign and institutional investors, have diverse information to access and more technique and hence are more rational in making investment decisions. However, the test results also show that B-share investors tend to herd in a down market due to their uncertainty regarding Chinese government frequent interventions. Lao and Singh (2011) provided the findings suggesting that herding behavior presence in both Chinese and Indian markets with difference herding

patterns. A recent study of Bhaduri and Mahapatra (2013) also discovered consistent findings of herd behavior in Indian equity markets. Presence of herding behavior in Asian equity market was also reported in recent works of Yao et al. (2009), Demier et al. (2010), Laih and Liao (2013).

In contrast to developed and emerging financial markets where literature of herding is plentiful, very few studies have been conducted in frontier markets. Chen (2013) performed investigation of herd behavior in 69 financial markets over 10 years using daily returns of 35,528 listed stocks. Based on the MSCI Market Classification Framework, 69 countries are classified into three groups: 23 developed markets, 20 emerging markets, and 26 frontier markets. The study employed different methods to examine the presence of herding including cross-sectional standard deviation developed by Christie and Huang (1995), cross-sectional absolute deviation suggested by Chang et al. (2000), and standard state-space model proposed by Hwang and Salmon (2004). The result shows mixed evidence of herding in different markets. To frontier markets, the evidence of herding is different with different methods and scenarios. With cross-sectional absolute deviation method, herding is found in most countries, except for Argentina, Bahrain, Bulgaria, Estonia, Kenya, Lebanon, Serbia, and Slovenia. However, the conclusion of herding is different under consideration of market scenarios.

Another trend of research on herding is to examine evidence of herd behavior within industry context. Demirer et al. (2010) argued that understanding herd behavior in industry framework is motivating because most of investment decisions and recommendations are taken place at the industry level. Bikhchandani and Sharma (2001) additionally proposed that herd behavior is likely to occur in industry level where market participants face similar problems and can easily observe the others' trade movement. In the study of Derimer et al. (2010), two testing methods namely return dispersion-based models and state space model are respectively employed to seek for the presence of herd behavior in industry context in Taiwanese stock market. Daily returns for 689 Taiwanese stocks traded on the Taiwan Stock Exchange over the January 1995–December 2006 period are classified into 18 different sectors. The results from the non-linear model and state space model consistently provide support of herding in all sectors. This is contrast to the results from linear model which indicates absence of herding in most sectors, with an exception of Electronics sector. Yao et al. (2014) also pay attention on investigating herd behavior at industry level. Based on the industry classification guidelines issued by the China Securities Regulatory Commission, 1314 stocks listed on Shanghai stock exchange and Shenzhen stock exchange are divided into 21 sectors. The regression results indicate strong presence of herding in most of sectors, except for agriculture, mining, machinery, financials, information technology, and conglomerate sectors. Different to the two mentioned studies, a recent study of Cakan and Balagyozyan (2013) only takes a look for evidence of herding in the Turkish banking sector. Using herding test proposed by Changet al. (2000) and daily stock turns from 2007 to 2012, they found the presence of herd behavior only in rising markets but also concluded that the herding in Turkish exhibits asymmetric effects.

### **3 DATA AND METHODOLOGY**

#### **3.1 Data**

Daily and weekly closing price of all listed companies on both HOSE (Hochiminh stock exchange) and HNX (Hanoi stock exchange) are collected during the period from 01/01/2007 to 17/10/2014. Return of stock  $i$  is computed as follow:

$$r_{i,t} = \log(P_{i,t}/P_{i,t-1}), \quad P_{i,t} \text{ closing price of stock } i \text{ at time } t$$

During the examined period, 772 companies are listed on both HOSE and HNX. Those companies are divided into 17 different industries. Oil industry only includes 4 listed companies which fail in representing the industry, and thus be eliminated from the study. Construction – material industry is comprised by the most listed companies with 207 companies, whereas retail industry has minimum listed companies at 10 companies. It is noted that from 01/01/2007 to 31/12/2010, the retail industry has fewer listed companies. Therefore, historical data for the Retail sector is only collected during the period from 01/01/2011 to 17/10/2014.

### 3.2 Methodology

Popular model used to examine herding behavior was proposed by Chang et al. (2000). This methodology basically utilizes cross-sectional dispersion of individual stock returns measured by the Cross-sectional Absolute Deviation (CSAD) which statistically defined as:

$$CSAD_t = \frac{1}{n} |r_{i,t} - r_{m,t}| \quad (1)$$

Where  $r_{i,t}$  is the daily logarithmic return for underlying asset  $i$ ,  $r_{m,t}$  is the return on the market portfolio for period  $t$ , and  $n$  is the number of stocks in the portfolio.

According to Chang et al. (2000), the rational asset pricing models implies that the level of equity return dispersions will increase when the absolute value of overall market returns increase since the volatility increases. In other words, there is a positive linear relationship between CSAD and market returns. However, if investors try to follow whole market behavior and ignore their own preferences during periods of large price movements, then the relationship between dispersion and market returns can increase in a decrease rate, or even decreasing if herding is severe.

To conduct a test for detecting herding behavior, Chang et al. (2000) adopt the following regression model:

$$CSAD_t = \alpha + \beta_1 |R_{m,t}| + \beta_2 (R_{m,t})^2 + \varepsilon_t \quad (2)$$

$$CSAD_t^{UP} = \alpha + \beta_1^{UP} |R_{m,t}^{UP}| + \beta_2^{UP} (R_{m,t}^{UP})^2 + \varepsilon_t \quad \text{if } R_{m,t} > 0 \quad (2a)$$

$$CSAD_t^{DOWN} = \alpha + \beta_1^{DOWN} |R_{m,t}^{DOWN}| + \beta_2^{DOWN} (R_{m,t}^{DOWN})^2 + \varepsilon_t \quad \text{if } R_{m,t} < 0 \quad (2b)$$

Where  $|R_{m,t}^{UP}|$  and  $|R_{m,t}^{DOWN}|$  are the absolute value of an equally-weighted realized return of all available securities on day  $t$  when the market is up or down and  $(R_{m,t}^{DOWN})^2$  is the squared value of this term. Under this model, if no herding activity exists in the market and the rational asset pricing models exist, the regression should demonstrate linearity, implying that  $\beta_2 = 0$ . Whereas a non-linear equation with a statistically significant negative  $\beta_2$  indicates a presence of herding.

Since a high level of serial autocorrelation is likely to exist in high frequency time-series market data, the failure to exactly address this problem will result in biased estimates of the parameters. Consequently, in addition to employ the heteroscedasticity and autocorrelation consistent standard errors suggested by Newey and West (1987) to estimate the regression coefficients, Yao et al.. (2014) suggest a modified model as follows:

$$CSAD_t = \alpha + \beta_1 |R_{m,t}| + \beta_2 \left( R_{m,t} - \bar{R}_m \right)^2 + \beta_3 CSAD_{t-1} + \varepsilon_t \quad (2c)$$

Where  $\bar{R}_m$  is the arithmetic mean  $R_{m,t}$ . The procedure  $(R_{m,t} - \bar{R}_m)$  will remove a small proportion of the multicollinearity between the explanatory variables in the regression equation, and thus will reduce the standard errors associated with the regression coefficients and increase the strength of the model. However, model of Chang et al. (2000) may cause structural multicollinearity between  $|R_{m,t}|$  and  $(R_{m,t})^2$  quadratic regression model. Therefore, we propose a modified model as below:

$$CSAD_t = \alpha + \beta_1 |R_{m,t}| + \beta_2 \left( |R_{m,t}| - \bar{R}_m \right)^2 + \beta_3 CSAD_{t-1} + \varepsilon_t \quad (3)$$

where  $\bar{R}_m = (1/n) \sum_{t=1}^n |R_{m,t}|$ . The procedure  $(|R_{m,t}| - \bar{R}_m)$  will remove a large proportion of the multicollinearity between the explanatory variables in the regression equation, and thus will reduce the standard errors associated with the regression coefficients and increase the strength of the model. In this model, the existence of herding behavior can be confirmed if  $\beta_2$  is statistically significant and negative.

Tan et al. (2008), besides examining herding behavior in Chinese stock market, additionally investigates whether actions of A-share investors have impact on B-share investors investment decisions, and vice versa. Hence, in this study, it is also interesting to test the existence of cross-exchange effects on herd behavior between HOSE and HNX. Particularly, we construct modified regression models based on the original models of Tan (2008) as below:

$$CSAD_{HOSE,t} = \alpha + \beta_1 |R_{HOSE,t}| + \beta_2 \left( |R_{HOSE,t}| - \bar{R}_{HOSE,t} \right)^2 + \beta_3 CSAD_{HOSE,t} + \beta_4 (R_{HNX,m,t})^2 + \varepsilon_t \quad (4a)$$

$$CSAD_{HNX,t} = \alpha + \beta_1 |R_{HNX,t}| + \beta_2 \left( |R_{HNX,t}| - \bar{R}_{HNX,t} \right)^2 + \beta_3 CSAD_{HNX,t} + \beta_4 (R_{HOSE,m,t})^2 + \varepsilon_t \quad (4b)$$

It is more evidences proving that developed market volatility may lead other markets. The impact is even stronger on developing markets. In a study of Chiang and Zeheng (2010), they found that events in the US market have noticeable effects, and to some extent help to explain herding in other markets. Therefore, the study further investigates for any impact of the developed markets, particularly U.S and Hong Kong stock markets, on Vietnamese stock markets and investors' herd behavior. Particularly, we adjust the models suggested by Chiang and Zeheng (2010) by simultaneously including squared market returns for the U.S and Hong Kong market in the regression model. S&P 500 index (SP500) is representative for the U.S market, whereas Hang Seng index (HSI) is chosen for Hong Kong market. Since the U.S stock market is traded haft day later than Vietnamese market, a one-lag variable for S&P 500 index is used as follows:

$$CSAD_t = \alpha + \beta_1 |R_{m,t}| + \beta_2 \left( |R_{m,t}| - \bar{R}_m \right)^2 + \beta_3 CSAD_{t-1} + \beta_4 (R_{US,t-1})^2 + \beta_5 (R_{CH,t})^2 + \varepsilon_t \quad (5)$$

where  $R_{US,t-1}$  and  $R_{CH,t}$  are the return on the SP500 and HSI for period  $t$ , respectively.

According to the model, statistically significant negative coefficients of  $\beta_4$  and  $\beta_5$  will strongly indicate an existence of herding in Vietnamese market causing by developed markets. If  $\beta_4$  and/or  $\beta_5$  are statistically significant positive, movements from the U.S and/or Hong Kong stock markets affect investor behavior in Vietnamese stock market. Whereas positive values of the coefficients reject the impact of developed markets and herd behavior.

Chang (2000) indicates that the existence of herding is different in up and down markets. Therefore, we estimate the regressions for detecting herding both market scenarios as shown below:

$$CSAD_t^{DOWN} = \alpha + \beta_1^{DOWN} |R_{m,t}^{DOWN}| + \beta_2^{DOWN} \left( |R_{m,t}^{DOWN}| - \bar{R}_m^{DOWN} \right)^2 + CSAD_{t-1}^{DOWN} + \varepsilon_t \text{ If } R_{m,t} > 0 \quad (6a)$$

$$CSAD_t^{UP} = \alpha + \beta_1^{UP} |R_{m,t}^{UP}| + \beta_2^{UP} \left( |R_{m,t}^{UP}| - \bar{R}_m^{UP} \right)^2 + CSAD_{t-1}^{UP} + \varepsilon_t \text{ If } R_{m,t} < 0 \quad (6b)$$

Klien (2013) argues that time varying affect herd behavior in stock market. For this reason, to investigate the power of research results, sample period is divided into two sub-periods, from 01/01/2007 to 12/31/2010 for the first period and from 01/01/2011 to 10/17/2014 for second period.

## 4 EMPIRICAL RESULTS

### 4.1 Statistical Descriptions

Tab.1 presents descriptive statistic of  $CSAD_t$  and  $R_{m,t}$  of each industry in the two stock exchanges. Maximum values of  $CSAD_t$  and  $R_{m,t}$  are found in Communication and Health industry, respectively 17% and 10%. Information technology industry has a minimum value of  $R_m$  at -7.81%. The Jarque-Bera test statistics are significant at 1% for both  $CSAD_t$  and  $R_{m,t}$  with an exception of Financial service industry. This leads to rejection of null hypothesis of a normal distribution both time series. The Augmented Dickey-Fuller (ADF) test statistics are significant at 1% for both  $CSAD_t$  and  $R_{m,t}$  cross all industries, indicating that the null hypothesis of a unit root can be rejected. On the other hand, both time series are stationary.

The coefficient of  $CSAD_t$  is higher than  $R_{m,t}$  in all industries with lag length respectively at 1, 2, 3, 15 and 20. To  $R_{m,t}$ , the coefficient declines with an increase of lag value up 20. With 1-lag,  $CSAD_t$  has a relative high coefficient value. The maximum value is 0.577 for Construction - material sector, whereas minimum value is observed in case of Car parts - accessories at 0.288. When lag length is increased from 1 to 20, coefficient of  $CSAD_t$  slightly decreases.

### 4.2 Empirical Results

Regressive results of Equ.(2) for all industries are provided in Tab.2. Except for Communication and Medical sectors, estimated coefficient  $\beta_2$  in other sectors is statistically significant negative, indicating that investors intend to herd in these sectors. Foods-Beverages and Tourist-Entertainment sectors have strongest and weakest degree of herding, with  $\beta_2$  of -9.4129 and -1.7883 respectively. However, Durbin –Watson results of all industries are smaller than 1.5, implying the possibility of bias in estimating parameters. Beside, all adjusted Rsquare values are less than 10%.

Tab.3 presents regression results for Equ.(3) of all sectors, and the three market portfolios. Results for three sectors include Tourist-Entertainment, Communication, and Medical show the absence of herding with insignificant coefficients. Other sectors yield a significantly negative  $\beta_2$  and estimates at 1% level. Foods-Beverages has the strongest degree of herding with  $\beta_2$  of -9.1168, whereas the weakest degree of herding is observed in Financial services sector. With modified model, Durbin –Watson values of all sectors are far greater than 1.8. Value of adjusted  $R^2$  is also higher, implying appropriateness of the model. Additionally, estimating results for HOSE, HNX, and all-stocks portfolio exhibit strong evidence of herding. The finding is in line with those found in the study of Chen (2013).

The results of the study indicate that herd behavior exists in both industry and market context. The finding hence strongly supports the conclusion of Bikhchandani and Sharma (2000) that herding behavior tends to arise at the industry level. The finding is also a strong evidence of

herding in industry level in a frontier market, which is completely different to the previous finding of Yao et al. (2014) and Demirer et al. (2010) who found herding in emerging markets.

*This table reports the estimated coefficients, t-statistics, adjusted R<sup>2</sup> and Durbin-Waston of the Equ. (3).  
\*\*\*, \*\*, and \* represent statistical significance at the 1%, 5%, and 10% levels respectively.*

Tab.4 and Tab.5 presents regression results for both sub-periods respectively. In the first sub-period, herd behavior is absent in three sectors including Financial services, Car Parts-Accessories, and Communications. Results for other sectors show strong evidence of herding with significant negative coefficients  $\beta_2$  at 1% level in most cases. It is noticeable that Medical sector only exhibits presence of herding in the first sub-period.

*This table reports the estimated coefficients, t-statistics, adjusted R square and Durbin-Waston of the Equ. (3).\*\*\*, \*\*, and \* represent statistical significance at the 1%, 5%, and 10% levels respectively.*

In the later sub-period, evidence of herding is not found in Retails, Medical, Tourist, and Entertainment with statistically significant positive  $\beta_2$  at 1% level. The others exhibit strong evidence of herding with negative  $\beta_2$  and statistically significant at 1%. In this sub-period, the degree of herding is very strong with all coefficient  $\beta_2$  smaller than -2.5. The herding is strongest in Car Parts-Accessories and smallest in Financial services with  $\beta_2$  of -8.4504 and -2.6233 respectively.

Due to the strong degree of herding found in the second sub-period, we further investigate investors' herding by dividing the second sub-period into two more sub-periods. Particularly, the first sub-period is from 01/01/2011 to 12/31/2012 and the second sub-period is from 01/01/2013 to 10/17/2014. Equ.(3) is estimated for the two sub-period and the results are respectively shown in Tab.6 and Tab. 7. In the first sub-period, strong herding is found in all sectors with high significantly negative  $\beta_2$  coefficients. However, the result indicates dissimilar findings in the second sub-period. According to the results disclosed in Tab.7, there are only seven sectors in which herd behavior is disclosed, including Real estates, Information technology, Financial services, Banking-Insurance, Car Parts-Accessories, Essential resources, and Construction-Materials. It is also worth noting that Tourist-

Entertainment exhibits no evidence of herding in both sub-periods. Banking- insurances, and Car Parts-Accessories show an existence of herding only in the second sub-period. Conversely, herd behavior is only found in the first sub-period in the case of Medical sector. Other sectors yield strong significantly positive  $\beta_2$  coefficients in the two sub-periods, indicating a presence of herd behavior.

Chang et al. (2000) discussed that the existence of herding may be a result of either a strong intervention of government relating to monetary policy or the impact of company's information disclosure on the financial market. In frontier markets such as Vietnamese market, the presence of inefficient information disclosure may provide market participants with lack of fundamental information. As a result, they tend to make their investment decisions based on other information, especially information relevant to industry. It is noticeable that, during the period from 01/01/2011 to 31/12/2012, evidence of herd behavior is strongly found in all sectors. A possible reason for this observation is that Vietnamese government announced much macroeconomic related information which has significant

impact on all sectors during this period. In other periods, macroeconomic information may affect some of the sectors only, causing the inconsistency of herding among the sub-periods.

Besides, in the study of Chang et al. (2000), adjusted  $R^2$  values were used to evaluate the impact of macroeconomic information and firm-specific information on investor behavior. They also argued that portfolio with higher adjusted  $R^2$  value indicates a higher influence of macroeconomic information compared to firm-specific information. Adapting to this dispute, the study further examines if macroeconomic information plays a relative important role than sector-specific information in Vietnamese stock markets. It is interesting that the results estimated from the modified models of the three market portfolios (all-stocks, HOSE, and HNX portfolio) indicate a higher value of adjusted  $R^2$  compared to adjusted  $R^2$  value obtained from all sectors. This implies that macroeconomic information may have a greater impact on investor behavior in Vietnamese stock market.

Tab.8 provides results for the existence of cross herding between HOSE and HNX during the studied period. HOSE is affected by HNX information but no conclusion on herd behavior can be drawn. On the other hand,  $\beta_4$  coefficient is equal to 0.9455 and statistically significant

at 1% level. It is interesting that herd behavior is very strong within HOSE market with statistically negative  $\beta_2$  coefficient of -13.7819. Conversely, HOSE market significantly affects herd behavior in HNX market with significant coefficient  $\beta_4$  of -3.6813. However, internal herding in this market is relatively low with  $\beta_2$  coefficient of -1.6288.

Tab.8 - Regression results of the daily CSAD on Equ. (4a) and (4b) for period from 01/01/2007 to 10/17/2014

Markets	Const.	$\beta_1$	$\beta_2$	$\beta_3$	$\beta_4$	Adj.R <sup>2</sup>	DW
HOSE	0.0097***	0.0456***	-13.7819***	0.5192***	0.9445***	0.4249	1.81
HNX	0.0102***	0.1087***	-1.6288***	0.5981***	-3.6813***	0.3928	2.18

*This table reports the estimated coefficients, t-statistics, adjusted R<sup>2</sup> and Durbin-Waston of the Equ.(4a) and (4b).\*\*\* represents statistical significance at the 1%.*

Tab.9 shows regressive result for Equ.(5). The result indicates the impact of other markets' information on herd behavior found in Vietnamese stock market. A negative and insignificant coefficient of -0.63 is observed in HOSE, indicating that SP500 has no impact on HOSE. In the case of Hong Kong market with HSI,  $\beta_4$  coefficient is 0.3594 and statistically significant at 1% level. The positive coefficient  $\beta_4$  implies that information from Hong Kong stock market have an effect on HOSE. Alternatively, SP 500 distresses HNX and all-stocks portfolios with  $\beta_4$  are -0.4856 and -0.3929, respectively. The two portfolios are also affected by information of HSI with statistically significant positive  $\beta_5$  at 1% level.

Tab.10 discloses regression results for Equ.(6a) and Equ.(6b) in both up and down market scenario for HOSE, HNX and all-stocks portfolio. The results indicate that herd behavior

exists in all market portfolios under both up and down markets. All  $\beta_2$  coefficients are statistically significant negative at 1% level. This implies that market participants react to both up and down market. By comparing the coefficients value of  $\beta_2$ , it is worth noting that herding tend to be stronger in the up market. Besides, HOSE portfolio exhibits stronger degree of herding compared to other two market portfolios. The finding is inconsistent to the study of Chen (2013) which indicates that there is no evidence of herding in both up and down market using CSAD method. However, Chen (2013) conducted the study during the period from 01/01/2007 to 31/12/2009 with the usage of original herding testing model suggested by Chang et al. (2000). Therefore, the inconsistency in findings may be caused by the difference in studied period and model employed.

## **5 CONCLUSIONS**

This study investigates behavior of investors in Vietnamese stock market during the period from 01/01/2006 to 17/10/2014. The original models proposed by Chang et al. (2000) were used to test herd behavior in 16 sectors and two market portfolio namely HOSE and HNX. Besides, modified models were also employed to remove multicollinearity and autocorrelation problems in estimating regression models.

By estimating the modified models and dividing the studied period into sub-periods, the study's results indicate an existence of herding in all sectors in Vietnamese stock market. Especially, five sectors which exhibit herding in all periods including Real estates, Information technology, Financial services, Essential resources, and Construction-Materials. When further testing the herding in a shorter period from 01/01/2011 to 31/12/2012, strong degree of herding is found in all sectors. Besides, the estimating results for all market portfolios specify the presence of herding in all periods.

Additionally, we use a modified model to capture any impact of international stock markets on investor behavior in Vietnamese market. The results show that herd behavior found in HNX and all-stocks portfolios are affected by the U.S stock market. In the case of HOSE portfolio, investor behavior is also affected by the U.S stock market but no conclusion of herding could be confirmed. Events in Hong Kong stock market have a relatively effect on HOSE, HNX and all-stocks portfolio but no evidence of herding was reported. In the other words, market participants in Vietnam always observe the market movement of U.S and Hong Kong. However, their investment decisions are likely to make based on the U.S movement.

Finally, investor behavior is driven by market scenarios. The study show that investors tend to herd in both up and down markets. This finding is consistent in all market portfolios. Besides, the study provides strong evidence showing that investors in HNX market are likely to herd based on the information from HOSE market. Conversely, movements from HOSE market do not lead investors to herd in HNX.

## **THE ECONOMIC VALUE ADDED ALGORITHM RISKS IN THE CONTEXT OF CORPORATE PERFORMANCE MEASUREMENT SYSTEM**

*Veronika Burešová, Lilia Dvořáková*

### **Abstract**

The paper presents the results of a partial research in the area of corporate performance measurement performed within the project SGS-2015-021 Development of financial management approaches as a tool of company value growth. It analyzes, evaluates and summarizes the advantages and limitations of the Value-Based Management concept (further just VBM) – a modern management approach that offers a rich potential for companies all around the world and across business areas about how to strengthen and keep their competitiveness. The risk analysis results are presented – the problems connected to the economic value added (further just EVA) algorithm, the obstacles for a clear EVA indicator quantification. Business entities should not neglect these problems, obstacles and risks if the set targets, for which the approach was introduced in the enterprise, are to be completed by the means of implemented VBM concept. In the context of corporate performance measurement risk management, the most attention in this paper is devoted to the topic of corporate capital costs determination. It is one of the most urgent problems during the implementation of VBM concept principles in corporate practice. At the end selected methodical processes (pricing models) which are used for corporate capital costs determination are discussed and critically evaluated. The main outputs of the performed qualitative research present the generalized recommendations and methodology support in the area of capital profitability evaluation and economic value added with a special focus on risk identification and analysis in the process of their quantification.

*Keywords: corporate performance measurement system, Economic Value Added, interest rate, risk, Value-Based Management*

### **1 INTRODUCTION**

It is possible to quantify the impacts of the planned (future) or the realized economic decisions of an enterprise by application of suitable methods and tools for corporate financial performance measurement. In the short time horizon (period of approximately until one year) the effectiveness of an enterprise as a whole (on the basis of the legally enshrined obligation of data in the financial statements publication) is researched. On the other hand (also in the short time horizon) the effectiveness of corporate parts, levels to the level of processes, operations and activities are researched as well; it happens on the basis of corporate sub-reports compared with budgets and forecasts and supporting managerial decision making. In the medium-term (period of 1 to 5 years) the business success and in the long-term outlook the competitiveness of the enterprise is researched, which is confirmed by the tendencies in the corporate practice development and also the conclusions of academic debates.

The topics of corporate value creation and management (in the optimization meaning) are still more getting in the corporate limelight. For an enterprise it is essential not only to achieve short-term performance (effectiveness the most often measured in conditions of the Czech

Republic by the financial analysis ratio indicators) but also the necessity to assure a sufficient reward for the current investors for their risk of investing their free capital in the enterprise, which they presume and demand to valorize at the best (as high as possible and as fast as possible) (IMA). Therefore the researched topic of this paper is the Value-Based Management (further just VBM) concept, namely the selected problems associated with the economic value added (further just EVA) concept - one criterion for corporate performance measurement of the VBM concept use in the short-term in corporate practice.

The corporate VBM concept together with the EVA indicator represents the major breakpoint in the view on corporate financial performance (Stewart, 1991, Venanzi, 2012, Mařík & Maříková, 2005). The meaning of VBM concept based management is to help the made managerial decisions to always have positive influence and impacts on the corporate value by a lot of instruments. As Ittner and Larcker (2001) present, in the current corporate practice the value management is ideally perceived as a complex system which integrates strategy, processes, corporate culture and also the analytic techniques for performance measurement (Knápková, Pavelková, 2005).

Out of the whole complex area of VBM this paper is specifically focused on the corporate performance measurement based on the quantification of the corporate EVA. For now let's forget the fact that the idea of economic value added is already used in the current corporate practice not only in the form of a „mere“ EVA indicator but also as a benchmarking tool, motivational element, for appraisal of the enterprise etc., thus as a comprehensive concept of economic value added produced by the enterprise. The theoretical basis of EVA indicator and its application beginning in the corporate practice in accordance with the main idea of VBM reflect the investors' effort to find such business entities by which there is the highest probability that their potential investment of these investors will lead to the growth of their wealth. Furthermore, the value of EVA indicator provides the enterprise for which is the EVA indicator calculated, the information, whether transaction of business sufficiently contributes to reward the existing owners and shareholders considering their expectations and possible investment alternatives.

In the first part of the paper a so-called one-scenario approach is presumed. The one-scenario approach is a very often feature in the corporate practice of the business entities in the Czech Republic. In corporate practice there is often worked with just one version of future development. Not only the small pro-export oriented economy of the Czech Republic is affected by the globalization tendencies, as some like to point out by turbulences and rapid development.

The EVA indicator value quantification is connected to a few problems which are analyzed in detail in this paper. The methodical processes (appraising models) how to quantify the risk as accurately as possibly are discussed and critically analyzed. They are the risks which the investors take by inserting their sources in a firm and thereby also the profitability necessary for the corporate value creation. How to minimize the risks associated with the EVA indicator algorithm, the indicator which appears to be an effective managerial tool for performance and effectiveness growth of a firm and for value creation for owners (shareholders)?

Some authors consider the financial performance and the economic performance to be synonyms; others strictly distinguish these two terms (Burešová & Dvořáková, 2013, 2014). The authors associate the financial performance with the traditional methods and tools for corporate performance measurement while the economic performance with modern concepts, methods and tools for corporate performance measurement.

## **2 THE RESEARCH PROBLEM SPECIFICATION, TARGETS OF THE PAPER AND USED RESEARCH METHODS**

The main target of the paper is to point out the pitfalls and problems associated with the economic value added calculation in the context of the reported values accuracy and correctness of this indicator in corporate practice. The risk analysis of EVA indicator algorithm is often neglected. A wide range of partial solutions versions exists within the EVA indicator calculation; it determines a high level of subjectivity in the financial decision-making and difficulties in benchmarking realization. Furthermore EVA indicator calculation procedure is not harmonized at the national level or in the worldwide context. That's why the problems associated with EVA indicator algorithm should be researched and discussed.

At first the benefits and the limitations of the VBM approach and EVA indicator will be summarized. The results of risk analysis will be presented. These risks should be taken into account by the business entity in management according to the VBM concept (approach), specifically according to EVA system regardless the subject (area) of business, product portfolio, corporate culture etc. It will be analyzed the problems associated with the calculation method of the EVA indicator, looked for a solution for identified problems and after various possible solutions will be discussed. Because one of the most urgent problems connected with EVA implementation into the corporate practice is the capital costs determination, also the usability of the methodical processes known in the financial theory (pricing models) for invested corporate capital costs determination in the conditions of the business entities in the Czech Republic will be evaluated.

On the basis of the problem definition the following basic **research questions** can be specified:

**Research question 1:** Does the methodology for the EVA indicator calculation provide accurate information about the corporate financial performance?

**Research question 2:** What kind of the valuation model for the own capital costs determining is for the EVA indicator calculation for the medium-sized enterprises in the Czech Republic the most suitable?

The outputs presented in this paper – the results of the partial research of a qualitative manner in the area of corporate performance measurement by the EVA indicator are achieved on the basis of critical literary search of local and foreign sources (book publications, professional journals, conference proceedings, research studies and information on websites, and mainly of available scientific and professional databases). Then the pair methods analysis-synthesis, the technique of analysis and comparison of scientific knowledge in the selected topic were used.

## **3 THEORETICAL BASES**

### **3.1 The comparison of the value-based indicators of the VBM concept with the traditional financial analysis tools**

The previously published international studies and performed researches (e.g. Bain & Company, 2011, Rigby & Bilodeau, 2013) show the results that economic value added (EVA indicator) and traditional financial analysis tools are the most famous and in the long-term steadily most often used in the corporate practice in the world context for corporate performance measurement in its financial management.

Although the small and medium enterprises (further just SME) in the Czech Republic are mostly aware of the clear advantages which the VBM concept and its subsequent methods and tools bring, a lot of them still use the traditional approaches – financial analysis methods and

tools – for the corporate performance measurement in spite of the increasing pressure and growing emphasis on competitiveness maintaining and strengthening. Within the financial analysis the most used is the ratio analysis (ratio indicators of rentability, activity, solvency/liquidity, indebtedness; or indicators of the capital market and productivity). Most of these indicators are monitored in a one year horizon (most often once a year), the selected indicators are then evaluated in time in terms of trend or within benchmarking (e.g. rentability and liquidity indicators).

The criticism of traditional indicators of corporate economy results from the conception barrier between the performance measured on the accounting data basis and market perception of the enterprise. The accounting results do not always correspond with the economic view on an enterprise.

As a result of weaknesses and limitations of the traditional financial performance measurement methods and tools in financial management there is an evident effort to find, enforce and introduce such indicators which could overcome objections to (mainly ratio) indicators of financial analysis (accounting indicators reflecting the financial effectiveness) – especially by including the time and risk factors into the corporate practice. The beneficial indicators with a high potential seem to be:

- indicators showing a close link to the shares value which should be statistically verifiable;
- indicators which enable to use as much potential hiding in the compulsory published accounting statements/annual reports of accounting units as possible – as large volume of information and data from the compulsory information subsystem of the enterprise (financial accounting) as possible;
- management accounting indicators measuring the managerial performance of the enterprise and enabling the streamline of the management of corporate activities, operations and processes.

Indicators which enable performance evaluation and corporate appraising at the same time also have an undeniable advantage.

The following advantages are associated with the modern indicators of economic performance compared with classical indicators of corporate financial performance (specifically e.g. EVA indicator):

- They provide more realistic information about corporate performance to the corporate management and at the same time they motivate the management to make decisions which would lead to firm's market value growth (EVA indicator works as a management tool);
- They evaluate the performance and effectiveness of corporate activities more accurately; the managers' interest in manipulating indicators decreases – e.g. EPS type (Earnings per Share), ROA (Return on Assets) or ROI (Return on Investment);
- They interconnect the interests of owners and managers better; involvement of the management in the economic value added growth simultaneously indirectly fulfils the interest of the firm owners. Thus the critical areas between the owners and the management are smoothed this way. Thus they contribute to removing the conflict of interest between the owners and the managers;
- They reduce the probability and impacts of intentional or unintentional manipulation with the reported level of economic result in accounting;
- They enable to reflect different risk level of corporate activities (financial and business risk, risk of corporate management etc.);
- They enable performance evaluation and also enterprise appraisal (EVA indicator has a strong link to the shares value, resp. the enterprise value, there is a close link between

EVA and MVA indicators);

- They can serve as the basis of the incentive systems for employees and for at least a rough inter-enterprise comparison.

The detractors often point out the following weaknesses of the VBM concept:

- The EVA indicator proceeds from the information and data of the corporate information subsystem – financial accounting (similarly to the traditional ratio indicators of financial analysis based on the retrospective evaluation of corporate performance). However data acquired out of the financial accounting subsystem are required too. Quantifying the result indicator value moreover requires a number of input data adaptations (accounting quantity of profit and invested capital) – to transform the accounting model to the economic model (Anderson, 2004, Venanzi, 2012).
- Apart from the difficult demands on data needed for the indicator calculation there is a large space for indicator result manipulation because it is necessary to be subjective while making the appraisal – especially of the capital costs and possibility of future expectations manipulations.
- The calculation of the own capital costs does not give a clear result even if more models are used.
- EVA does not work with the market values of corporate assets – thus does not express the real value creation, but again an accounting reality, however adapted.
- It is usually true that the higher EVA indicator value is the higher value the enterprise creates for the owners. However there are cases when the increasing EVA does not necessarily have to lead to corporate value rise. For example it happens in case when EVA increase at present was achieved at the expense of future super profits. It means that at corporate evaluation it is not possible to take into account just the EVA value at the present time (at the monitored and analyzed period) but it is necessary to predict the future development and the EVA indicator values. It is known and proved the dependence of the EVA indicator value on the corporate life cycle.

## **4 RESEARCH RESULTS**

### **4.1 Problems associated with EVA indicator algorithm**

Regardless in which form it is decided to quantify the EVA indicator value and to monitor its development, it is always necessary to remember the problems which come with the effort to quantify two values – NOPAT and WACC. Just these two quantities determine the result value of EVA indicator and the informative ability and accuracy of the calculated EVA depend on them.

Problematic points at the EVA indicator calculation can be summing up into these main categories:

1. NOPAT quantification
  - a) Operating economic result quantification.
  - b) Legal entities income tax rate determination.
2. WACC quantification
  - a) Other capital costs quantification.
  - b) Own capital costs quantification.
  - c) Own capital value determination.
  - d) Other capital value determination.
  - e) Legal entities income tax rate determination (t-tax(es)).
  - f) Determination of risk-free level profitability.

NOPAT is the profit from operation activity. However Czech accounting regulations (specifically the accounting law, implementing decrees, Czech accounting standards) do not know it in an explicit form. It is not possible to correctly identify NOPAT with any exact output of financial accounting – operating economic result (e.g. EBIT, EBDIT etc.) or an economic result in a common period (e.g. EAT). The reason is that EBIT, EBT or EAT and others can contain components which are not related to operation assets. The EBIT, EBT or EAT values can be influenced by not only the operation revenues and costs but also the costs or revenues from financial operations and transactions or special events impacts. As Kislingerová (2001) states in a contrast NOPAT is a quantity which reflects the real economic benefit of the enterprise for its owners from the main (operating) activities. The capital is the assets related to the corporate operation activity. The operation activity of an enterprise depends on the exact conditions and situation in which the company operates (it usually is the main activity/business area). In this context Mařík (2003) points out the necessity to keep the relations between operation assets and the economic result achieved by the operation activity.

The size of Weighted Average Cost of Capital (WACC) - an actual minimum required rate of return that must be achieved minimally in an enterprise, is influenced by the costs of individual (partial) kinds of capital which the main corporate (operation) activities are financed by and the share of these individual capital kinds on the total volume (value) of capital. The result WACC value is a weighted arithmetic average of costs on individual items of corporate capital; when the scales are these capital items' shares on the total capital.

#### **Risk-free level of profitability determination ( $r_f$ )**

One of the first problems which is brought by the quantification of invested capital costs (discount level) is the risk-free level of profitability determination. Although the pricing models/methodical procedures of quantification of problematic own capital costs work with the risk-free revenue rate in various forms, they use various „risk-free“ assets or assets burdened with minimal (the limit is near zero) risk level, in fact there is nothing like entirely risk-free assets (in other words assets whose profitability is burdened by zero risk) (Gavřáková, Kormanáková & Rypáková, 2014, Mařík & Maříková, 2007). It is difficult to find an asset, whose rate of return is burdened with zero risk - therefore there is no risk of default, minimum risk of non-liquidity, the minimum risk arising from their subsequent reinvestment after the time of maturity. But still the risk-free assets and also the risk-free level of profitability are valuable tools and instruments at certain presumptions (Pratt, 2008).

The financial theory offers a few ways how to proceed during the risk-free rate determination, what basis to choose for the follow-up EVA indicator quantification calculations. However, it is always necessary to observe the symmetry from the point of view of time, at which the funds are to be invested. For the risk-free rate it is always necessary to find such assets, whose maturities would correspond to the "life" of the enterprise. In the case of business incomes it is considered with generating revenues for the stage, on which the financial plan is drawn up (the so-called first phase), or to which the maturity of the corporate bonds is added and for the follow-up, time no longer unlimited horizon (so-called the second phase or perpetuity). In the ideal case, the risk-free rate of return should be set separately for each year of the first phase and for the second stage. In practice, however, companies have not applied it so far.

#### **Other capital costs determination ( $r_d$ )**

Other capital costs are determined as a weighted average of the effective interest payments (rates) which the enterprise pays from various forms of other capital (Mařík, 2003, Mařík & Maříková, 2007, Pratt, 2008). It is necessary to avoid a few pitfalls.

1. It is necessary to calculate just the costs of interest-bearing other capital which was

used for operation assets financing (e.g. loans, obligations, leasing financing etc.).

2. The assets which take part at the main operation activity have to be appropriately matched with the financial sources and then they have to be correctly appraised. Therefore the other capital costs need to be matched with the implicit interest rate contained in the leasing payments if the enterprise uses the leasing services.
3. On the contrary the other capital value is reduced by the interest earning liabilities (obligations to suppliers) because it is presumed that these obligations payments are included in the operation cash flows.
4. The values of individual capital items are transferred from corporate accounting reports – balance sheets, in accounting values. Thanks to the not very developed capital market in the Czech Republic compared to the capital markets in the Anglo-Saxon countries, it is very difficult to find out their market prices.

To determine the payments for other capital is thoroughly easy because they are generally strictly determined during making the relevant agreements. Therefore it is usually easier to determine the other capital costs than it is to estimate the own capital costs. However the data contained in the loan agreements (interest rate) needn't correspond with the market data. Hawawini (2002) recommends the enterprises which have issued obligations to calculate the revenues until the maturity date, which detects the other capital costs for the eminent. If the enterprise did not issue obligations, it is possible to approximate its other capital cost by the revenue of bonds traded on the market by an enterprise with the same rating (Mařík & Maříková, 2007). It is quite easy to find out the average interest by bank loans if the concluded loan agreements where the enterprise agreed on fixed interest rates are known. Then it is the weighted arithmetic average. However if it is an interest bound to an announced rate PRIBOR (Prague Interbank Offer Rate) or LIBOR (London Interbank Offer Rate) with a fixed percent surcharge, it is necessary to know the rating evaluation of the enterprise with the prognosis of the basic macro-economic indicators.

### **Own capital costs estimation ( $r_e$ )**

Although a lot of business entities behave as if the own capital was provided free of charge, it is not correct and it is necessary to calculate the own capital costs on the basis of the most credible method and to estimate them as accurately as possible. The own capital costs  $r_e$  are determined by the revenue expectations of the enterprise owners while their objective nature is the use of opportunity costs category. It is necessary to consider the revenue from other (unused) investment opportunity with the same level of risk for the own capital. But how to find one? And how to elaborately work with profitability and missed opportunities of investors when each has different preferences?

The value indicators take the risk factor into account. The risk is calculated until the appraisal either by adaptations/determination of risk surcharge into the discount level which is the more common version in corporate practice (and therefore it will be preferred in this paper), or by projected revenues adaptation – by the income reduction or as the case may be by the increase in expenditure components of cash flows due to the most likely estimates (so-called assurance coefficients). The use of a specific method depends especially on the availability of needed data. Before the data filling of the model itself it is necessary to find true answers to these types of questions:

- What are the markets conditions like? How developed are the markets where the researched enterprise operates?
- Is it possible to use and insert the data and information into appropriate models without problems and additional adaptations? If not, why and how will it be necessary to adapt the

data?

The choice of method for the own capital costs determination depends also on the legal form of business. If a joint-stock company is evaluated, to choose an appropriate method the essential fact is whether the shares of this business entity are traded on the capital market or not, which brings us back to the previous questions. In other words the nature and character of the market are the determiners of suitable methods for e.g. enterprise appraisal or corporate performance quantification.

The financial theory (e.g. Pratt, 2008, Dluhošová, 2004, Hawawini, 2002, Kislingerová, 2001, Copeland, 2000, Brealy & Myers, 2000, Ross, 1976) presents following ways for the own capital costs calculation, if we work with the risk surcharge as an indirect way to appraise the risks. The first group of models consists of approaches based on market data and taking into account only the systematic component of risk.

- CAPM Model (Capital Asset Pricing Model) – in the Czech Republic specifically e.g. CAPM-SML model beta version;
- APM model (arbitrage pricing model)/APT model (Arbitrage Pricing Theory);
- Dividend model DDM (Dividend Discount Model) also called the model of discounted dividends/Gordon's growth model (Gordon's model for stable growth).

The other group of models (so-called the build-up models) is based on the expert method of the cost of capital or the risk premium determining. The surveyed company's risk is evaluated by the use of a wider set of financial and non-financial risk factors. The build-up models take into account these types of corporate risks – the financial and business risks, not only systematic, they calculate the unsystematic (specific) risks as well. Thus they try to reach a higher level of objectivity in the determination of the cost of equity, the discount rate and ultimately the final value of the EVA indicator.

- Methodics of Garnett&Hill Company.
- Build-up method – In the Czech Republic specifically e.g. modular way/model according to Neumaierová et al (methodics of Ministry of Industry and Trade of the Czech Republic).

#### **4.2 Comparison of selected pricing models for the own capital costs determination ( $r_e$ )**

For the Anglo-Saxon countries and other economies with developed capital markets it is typical to use the capital asset pricing model CAPM (Sharpe, 1964, Lintner, 1965) or the APT model for the own capital costs estimation. Compared to the build-up approach within the surcharge method these models are connected to the market value of the enterprise. The Gordon's dividend model is appropriate for the enterprises which issue dividends to their shares. However for its weaknesses and too narrow use (Mařík & Maříková, 2007) it is not the topic of this paper.

##### **CAPM Model**

The capital asset pricing model (further just CAPM) in its general shape and form is based on a few assumptions (Kislingerová, 2001) which do not reflect the current capital market state, as is often reproached to the model authors. Although this model is often described as highly theoretical and detached from practice, as a result of these points of view – paradoxically – a lot of studies and empiric researches confirm this model to be a reliable tool for investors.

CAPM is based on the objectively observable inputs obtained from market data and, therefore, the market valuation of the risk. CAPM is based on inputs from highly developed and liquid capital market(s).

The risk of the model is quantified by a standard deviation of securities profitability from the average revenues. For the practical application of CAPM the least problematic seems to be the use of the expected long-term average of short-term treasury bills. But still the corporate practice clearly confirms that the long-term government bonds are a suitable basis for its use. The result value of CAPM can be significantly influenced also by:

- The risk-free rate value of profitability ( $r_f$ ).
- The value of the expected revenue of all market ( $r_m$ ) – can be determined on basis of the global index PX50 value or also by the country rating evaluation. The second possibility seems to be more suitable in view of the insufficient maturity of the capital market in the Czech Republic.
- The value of the market risk bonus (RMP) which is influenced by following factors:
  - Average revenues determination at the representative market index (e.g. PX50).
  - Risk-free asset revenue.
  - The security character.
  - The length of researched period.
  - The variability of revenues entering the calculation – calculation by arithmetic or geometric average.

The CAPM concept requires the difference ( $r_m - r_f$ ) to be expressed in expected values. However, a direct estimation of a future bonus is not possible and therefore the estimation of a future bonus (RMP) is often performed on the basis of the past value results achieved on capital markets. We assume that the past offers sufficient/appropriate estimation for the future development.

- The value of coefficient  $\beta$  – market risk  $\beta$  which is the scale of systematic risk. Mařík (2003) presents three basic ways how to estimate the  $\beta$  coefficient:
  - Procedure I usability – based on the past results (so-called historical  $\beta$ ) in corporate practice it is limited. We implicitly assume that the future, calculated  $\beta$  will not much differ from the historical value  $\beta$ .
  - Procedure II – analogy method is based on using the known value of coefficient  $\beta$  of similar business entities which are traded and whose activity is defined as non-diversified by an appraiser. Although there are searched the most similar business entities to the analyzed enterprise, we always have to count with certain differences. There are no two absolutely identical enterprises, enterprises with the same characteristics – business and financial risk. Therefore it is necessary, based on the expert estimation, to estimate/calculate the influence of these possible differences in business risk and financial risk which depend on the capital structure and take this into account in further calculations. Another version of the stated procedure which can also be used in practice are the average data about  $\beta$  for a certain business field or sector where the firm operates. The requirement to respect eventual differences between the analyzed business entity and the prevailing tendencies in the sector and their consideration in the calculations is also valid here. The average coefficients are presented either as indebted or as non-indebted. It is recommended to recalculate them in a specific capital structure of the researched enterprise.
  - Procedure III – estimation by independent prognosis is preferred in the corporate practice of Anglo-Saxon countries, in American firms practice.

This model has to be suitably adapted to the conditions of the concrete economy if it is made an effort to use the CAPM in enterprises' environment in the Czech Republic or in another economy with underdeveloped capital market. This is realized e.g. applications in the risk premium of the country in which the analyzed business entity operates. Further, it is

appropriate to take into account following situations and associated risks - the limited marketability of shares and stocks, the size of the enterprise, where appropriate, specific risks. The CAPM does not take into account the greater risk (rate of return) for companies that are smaller than big corporations. Therefore, it is necessary to take into consideration these differences that the CAPM fails to affect and to adjust the surcharge for market capitalization.

The risk premium of the country relies on the rating valuation of the country, which is through the difference of return of corporate bonds with the same rating as the country and the return of U.S. premium bonds factored into the risk premium of the market. This difference already involves a greater risk of investing in smaller Czech enterprises in comparison to larger U.S. evaluated companies. Risk and expected return associated with the incomparably smaller market capitalization of companies of the Czech economy compared to the companies in the U.S. it is therefore included in the margin for the risk of the country.

### **The APM model (the arbitrage pricing model) ~ the APT model (APT model – the arbitrage pricing theory model)**

The arbitrage pricing model APT is a more modern alternative of the CAPM model which brings the similarity of the advantages and weaknesses to the CAPM model. The ATP method is based on the three following assumptions (Kislingerová, 2001):

- it is possible to identify a limited number of macroeconomic factors,
- it is possible to measure the bonus for the expected risk for individual factors,
- it is possible to measure the sensitivity of each share to specific factors

The expected shareholder's revenue depends on the risk level coming from the general economic phenomena, not only from a unique specific risk. The APT theory is based on the same idea; in this aspect the APM model is similar to the CAPM model. However, in the CAPM model theory the bonus for risk depends on just one factor (coefficient)  $\beta$ , whereas in the ATP theory this bonus depends on a few macroeconomic factors – e.g. the inflation level, the economic activity level in the sector. Not only this applies that the APT theory requires a relatively wide information base which is one of the significant weaknesses.

### **The build-up model**

The build-up models are based on considering the risk in the form of risk surcharge, similarly to CAPM, APT, DDM models and others. The basis for discount rate calculation is again the risk-free level of profitability ( $r_f$ ). A specific feature of the build-up models is the fact that the risk bonus is the sum of specific items depending on the nature and level of risk of the researched/appraised enterprise.

In the conditions of little developed, insufficiently liquid and allocation inefficient capital market (this state is e.g. in the Czech Republic and other countries of the Visegrad system), the exact use of the capital assets pricing model (CAPM) and other methods based on the capital market (APT, DDM etc.) seems complicated. Therefore the Ministry of Industry and Trade of the Czech Republic created the INFA model which also belongs to the build-up models group of the own capital costs estimation and which is adapted for the specific conditions of a capital market of a small open economy of the Czech Republic. The own capital costs (calculated interest rate) according to the INFA model are calculated similarly to the classical build-up method, thus as a sum of the risk-free revenue level ( $r_f$ ) and the risk bonus (risk surcharges).

The main obstacle of the build-up model use for the own capital costs estimation ( $r_e$ ) is that the risk surcharges (RP) are often estimated from the accounting data but the EVA indicator is built on „economic“ quantities.

### The EVA factor model

The EVA factor model is built on the principles and the main ideas like e.g. the CAPM model. We can say that it is its wide-spread version. The EVA factor model develops the CAPM model in the sense that it attributes a lower level of the own capital costs ( $r_e$ ) to the enterprises with the stable positive value of EVA indicator than to the enterprises with volatile economic value added.

EVA factor model was created by authors Grant and Abate (Abate & Grant, 2001) with the target not to build the inputs on traditional accounting data (Grant, 2003, str. 223-231). The EVA factor model contains the systematic market risk (included in  $\beta$  from the CAPM model) as well as three systematic non-market factors (see formula 1):

$$r_e = CAPM + b_1 Size + b_2 NPV / Capital + b_3 SD_{EVA} \quad (1)$$

The factor *Size* corresponds to the market capitalization, the *NPV/Capital* ratio indicates the ability (or inability) of the enterprise to invest in value creation projects, *SDEVA* is a standard deviation of the economic value added (EVA). *SDEVA* indicates the stability in economic profits achievement. The  $b_i$  coefficients represent the risk bonuses related to specific factors.

It is true that the risk enterprises should be penalized by higher costs of the own capital ( $r_e$ ) for their inability to create value (the value of *NPV/Capital* ratio is negative) and a high volatility during economic profit creation (*SDEVA* is positive).

A great weakness of this model is the insufficient amount of empiric researches which would specify how to exactly determine the  $b_i$  coefficient. It is necessary to know the level of the statistic dependence among individual factors, especially between *SDEVA* and *NPV/Capital*. Because it is a question what would the model informative ability be like if the model did not contain the *SDEVA* factor?

## 5 DISCUSSION

The paper summarizes the main knowledge in the current corporate practice which is related to the best known and most used pricing models (methodical approaches) for the discount level quantification as a reward to the investors for the risk they take by investing their free finances and concurrently the capital costs from the enterprise point of view. The authors specifically focus on the advantages and limitations of the researched models. The capital costs quantification is one of the important problems which we have to face if we want to quantify the EVA indicator level.

The first problem is the choice of the appropriate risk-free asset and on this basis, the derivation of the risk-free rate. It is usually recommended to start with the use of either long-term state treasuries with 10-year or 30-year time horizon (as long-term financial instruments) or state treasury bills (as short-term financial instruments). During the use of the long-term instruments revenue rate there is a problem to estimate the purchasing power of these securities in the maturity period of the treasuries. Also in the case of the other possibility application – the use as the risk-free revenue value of the state treasury bills profitability, which are issued by the state apart from the long-term securities, there is a problem with the time perspective. The short-term risk-free rates significantly determine the corporate value because they form the major part of capital costs; this value is then very sensitive about the movements of short-term interest rates and macroeconomic quantities (gross domestic product etc.).

In spite of a lot of differences the demonstrated models are connected by the way how they

integrate the risk and the uncertainty into the corporate performance measurement system or corporate pricing (Fotr & Kislingerová, 2009). Respecting the risk factor has various forms of risk bonuses (RP).

It is clear, that all the assumptions for non-problematic quantification of specific CAPM and APT models components have not been achieved on the capital markets of the post-communist countries of the Central Europe (Visegrad group countries). Nevertheless, we can claim that after some adaptations also these models using and based on the data from developed capital markets can be used in economies with less developed market.

The one-scenario approach is a very often feature in the corporate practice of the business entities in the Czech Republic. In other words, they often work with just one version of future development in corporate practice. Not only the small pro-export oriented economy of the Czech Republic is „affected“ by the globalization tendencies, as some like to point out by turbulences and rapid development. All this determines the high level of uncertainty and also risks. Therefore it is more than adequate to think in the dimensions of a several-scenarios approach, work with versions of future development (Špaček, 2012). To know how the enterprise can develop on its best and how it can fall in terms of performance at the worst. And to be ready for these eventual versions. It is necessary to move away enough (in corporate managers' case) from excessive optimism, imaginary pink glasses by which the management workers see their enterprise (Fotr & Švecová). To define what we already know about the future development (i.e. trends) and to define and to describe what we know (i.e. the key uncertainties). Because this is the foundation and bases for scenarios creation (Fotr, Špaček, Souček, Vacík, 2015). However, the nature of risk factors matters too. It is sometimes appropriate to use the technique of simulations instead of the scenario approach. The simulation approaches are suitable in case there are a lot of risk factors of related or discreet nature, while we cannot presume significantly different possibilities of these factors development.

Whether the enterprise chooses the way of simulations or scenarios of the future development, the positive result is always the deeper reflection, more detailed analysis of possibilities which the enterprise has, the threats which can endanger the business entity potentially and the ways how to deal with it and to face the turbulent times with the target to achieve permanent competitiveness in the global competition.

## **6 CONCLUSION, RESEARCH BENEFITS NAD LIMITATIONS**

Based on the comparison of traditional and modern principles of corporate performance measurement, the paper summarizes the most essential reasons why the business entities (not only the Visegrad group but in global context) should implement modern indicators (e.g. EVA indicator of the Value-Based-Management approach) apart from the classical (traditional) indicators in their performance measurement system.

The next key output of the paper is the thorough analysis of risks and pitfalls related to the EVA indicator algorithm. The problems at quantification of NOPAT and WACC values were researched in details. Unfortunately for now the financial theory nor the professionals from corporate practice have not found the one universally used solution, or a few potentially optimal solution ways which would make the whole process of economic value added quantification easier and clearer – especially the WACC quantification.

The attention was further focused on the summary of advantages and limitations of the most often applied pricing models and methodical approaches in the corporate practice, how to determine the own capital costs value. The determination (estimation) of the own capital costs value represents one of the biggest problems at EVA indicator calculation for business

entities.

The build-up method approach is based on the investment value of a selected enterprise, when the calculated risk is bound to accounting, not market data and values. The INFA method (or the complex build-up method) belongs in this category. This approach and methods within its frame are suitable for countries which do not have a developed capital market. The methods based on developed capital market data (e.g. CAPM, ATP etc.) have a high future potential. Therefore we can presume that they will find their solid position also in the countries with not so advanced capital market in the next few years. In the corporate practice in the Czech Republic it is proved by modifications of models adapted for the Czech business environment.

The EVA factor model, which was also mentioned in the paper, tries to solve the limitations offered by the fact that in majority of the models inputs are built on the traditional accounting data. The Czech Republic does not abound in sufficiently liquid, effectively functioning capital market. There is the question how sufficient is the usability and reliability of the data obtained from such capital market. We can recommend for the basic CAPM equation to use the USA market bonus as the capital market risk bonus and to adjust the CAPM model with the current country risk. Then the formula determining the quantification would have the following structure:

$$r_e = r_f + \beta \cdot RMP + r_{země} + b_1 Size + b_2 NPV / Capital + b_3 SD_{EVA} \quad (2)$$

The factor *Size* corresponds to the market capitalization, the *NPV/Capital* ratio indicates the ability (or inability) of the enterprise to invest in value creation projects, *SDEVA* is a standard deviation of the economic value added (EVA). *SDEVA* indicates the stability in economic profits achievement. The  $b_i$  coefficients represent the risk bonuses related to specific factors.

As a follow up to the results of this qualitative research **the quantitative part of the research** will be subsequently realized. Its aim is to verify the use of the above mentioned valuation methods in practice in the environment of medium-sized manufacturing companies in the Czech Republic. The research sample of companies amounts to 87 enterprises (43 respondents were from the Karlovy Vary Region and 44 respondents were from the Pilsen Region). The questionnaire survey was selected as the most suitable form how to obtain data within the quantitative part of the research. With regard to the nature of the solved problem in the field of entrepreneurship in the Czech Republic, cooperation was established with the willing staff of corporate finance department; in particular, with employees of the financial accounting or controlling department and with the executive management (chief executive officers, chief financial officers) as well.

The electronic form of questionnaires was selected; the questionnaires were sent to the e-mail inbox of respondents; the completed questionnaires were sent by e-mail back to the e-mail address of the researchers. One of the biggest advantages of sending out the questionnaires is the fact that questionnaire survey is one of the fastest and most economic forms of data collection. On the contrary, a few problems can be also identified – i.e. the need to ensure the access to technologies enabling convenient filling in the questionnaire. Another (and much more significant) limitation is linked to the target group of respondents - a longer feedback period in comparison with other research forms of data collection (e.g. interviews, where feedback is immediate).

## **MODELS PREDICTING FINANCIAL DISTRESS AND THEIR ACCURACY IN THE CASE OF CONSTRUCTION INDUSTRY IN THE CZECH REPUBLIC**

*Dagmar Čámská*

### **Abstract**

Corporate financial distress and risk of bankruptcy may not lead only to a market exit of an ailing company but it can seriously influence also business related entities or counterparties. This reason raises the need to have tools which can help predict future environment and decision making process. Models predicting corporate financial distress as well as called bankruptcy models are an example of these tools and methods. Last global economic crisis has again renewed the scientific debate about appropriate accuracy of bankruptcy models. This paper is focused on an explanatory power of models predicting financial distress created in the past. Dozens of models are tested in the case of construction industry which has been highly affected by the last crisis. The paper should answer several questions. The question 1 is if the explanatory power of bankruptcy models created in the past is sufficient for decision making process. The question 2 is which models have the highest accuracy and which should be recommended for practical use. According to results connected with previous questions we can answer if there is a need of a new predicting tool. Statistically significant data sample is used for this research. Dozens of models predicting financial distress are verified by tools as Type I Error, Type II Error, ROC Curves and related AuROC coefficients.

*Keywords: financial distress, bankruptcy models, construction industry, Czech Republic*

### **1 IMPORTANCE OF MODELS PREDICTING FINANCIAL DISTRESS**

Prediction of corporate financial distress is a research topic which has inspired economists as Altman (1968) or Beaver (1966) since 1960's. Corporate financial distress is a serious risk which can lead to a corporate bankruptcy which influences also many other related entities. If the entity regularly monitors its own performance and development there is no need for special tools as models predicting financial distress providing a quick and inexpensive answer. These models are designed especially for other related entities as suppliers, customers, banks or another financial institutions, government etc. These partners use these tools for predicting future development of evaluated companies. It supports their decision making process and choosing right strategy how to achieve their own goals. It need not be emphasized that business with an ailing partner can lead to the threat of own viability.

There have been created plenty of models and tools predicting financial distress since 1960's. It is not possible to cover all of them because many methods were not published because they are part of entities' know-how in the case of banks and other financial institutions. The scientific debate about appropriate accuracy of models predicting financial distress is usually renewed by serious shocks and changes which is the case of the last global economic crisis. This paper introduces dozens of models predicting financial distress. Second it seeks to answer the question if there are models with appropriate accuracy and explanatory power which can be used nowadays for evaluating performance and development of the related entities.

## **2 THEORETICAL BASIS**

The financial viability as a key issue for every company because the company is not possible to survive in a long run in the case of its poor financial performance. In the long run the poor financial standing results in a bankruptcy. Kapliński (2008) summarizes components on which financial standing depends – the company's financial structure, financial liquidity, solvency, the company's capability to adapt, economic sources, capability to generate profit, capability to maximize the company's market value. Models predicting financial distress are created on the base which can be characterized as follows. It is possible to separate companies with high and low risk of the bankruptcy according to their financial performance displayed in financial statements. As it is mentioned above there has been created plenty methods predicting risk of the corporate bankruptcy. This paper uses as a theoretical basis dozens models predicting financial distress which have been created since 1960's. These models can be generally characterized as follows. They are tools using for prediction the data from the financial statements. The models were created using data samples and statistical methods such as linear discriminant analysis or logistic regression. Most verified models use for evaluation two or three zones (healthy, gray and unhealthy but there are also exceptions using more than three zones for final evaluation. The used models come from different historical, economical, political and geographical background how it is discussed immediately.

The paper is focused on the Czech Republic and therefore the Czech approaches form the core of verified models. The Czech Republic is represented by the family indices IN – IN99, IN01 (Neumaierová and Neumaier, 2002) and IN05 (Neumaierová and Neumaier, 2005), followed by Grünwald Bonita Index (Grünwald, 2001) and Balance Analysis System by Rudolf Doucha (Doucha, 1996). In recent years new models have been developed as Karas & Režňáková (2013) or Hálek (2013) approaches. These models are not verified in this paper because of reasons mentioned in Čámská (2014). The developed economies are represented by the models which are widely used in the Czech Republic as Altman Z-Score (Altman, 1993), Bonita Index (in the German original Bonitätsanalyse, Wöber and Siebenlist, 2009) or Kralicek (Kralicek, 2007). The developed economies have had a different economic and historic development compared with the Czech Republic which has on the other hand the comparable political and economic development as other transition economies. Transition economies are represented by Poland and Hungary as members of Visegrád Group and Baltic states (Latvia, Lithuania and Estonia) in this paper. In the concrete words the Polish models are Hadasik (Hamrol and Chodakowski, 2008), Holda (Pociecha, 2005 and Hamrol and Chodakowski, 2008), Gajdka & Stoda (Kisielinska and Waszkowski, 2010 and Hamrol and Chodakowski, 2008), Prusak (Kisielinska and Waszkowski, 2010), PAN-C, PAN-D, PAN-E, PAN-F, PAN-G, Wierzba, Poznanski, D1, D2, D3, D4 (all previous discussed in Kisielinska and Waszkowski, 2010), Apenzeller & Szarzec, Pogodzinska & Sojak, Sojak & Stawicki (all previous discussed Hamrol and Chodakowski, 2008). The Hungarian models are created by Hajdu & Virág by the discriminant analysis as well as the logit model (Hajdu a Virág, 2001). The Baltic models are Šorins & Voronova (Jansone, Nespors and Voronova, 2010), Merkevicus (Merkevicus et al, 2006), two factor model (Koleda and Lace, 2009), Stoškus (Stoškus et al, 2007), Genriha & Voronova (Genriha, Pettere and Voronova, 2011) and R model (Davidova, 1999). According to the literature some transition models are known in more versions and therefore all known versions are verified. The models' formulas are not displayed in this paper because it is not possible due to its page range. The model's formulas could be found in the related literature which is mentioned.

### **3 OBJECTIVES AND METHODOLOGY**

This chapter is focused on the paper's objectives and used research methodology and therefore it would be divided in the following subchapters as Paper's objectives, Research methods, Analyzed industry branch and last chapter will be dedicated to a definition of the surveyed companies. The paper should answer several questions which will be discussed in the subchapter Paper's objectives. The subchapter Research methods described the methods which are used for fulfilling the paper's objective as type I error, type II error, ROC curves and related AuROC coefficients. The verification is done on one chosen industry branch. The reasons and importance of this industry branch are discussed in the third subchapter. For the fulfilling Paper's objectives there have to be chosen appropriate companies which can be distinguished as companies with low and high risk of bankruptcy. The definition of the surveyed companies is included in the subchapter number 4.

#### **3.1 Paper's objectives**

The paper should answer several questions. The question 1 is if the explanatory power of the bankruptcy models created in the past is sufficient for the decision making process nowadays. The concrete verified models are displayed in the previous chapter. There are 40 different models' formulas. The question 2 is narrowly connected with the previous question because the questions finds which models have the highest accuracy and which should be recommended for practical use. According to results connected with the questions 1 and 2 we can answer if there is a need of a new predicting tool or we are satisfied with the results provided by the already created models predicting financial distress.

#### **3.2 Research methods**

This paper verifies accuracy and explanatory power of the different model predicting financial distress. The models' quality and performance can be measured and compared by several metrics. Sobehart, Keenen and Stein (2000) provide following tools:

- Cumulative Accuracy Profiles (CAPs),
- Accuracy Ratios (ARs),
- Conditional Information Entropy Ratio (CIER),
- Mutual Information Entropy (MIE).

On the other hand Basel Committee on Banking Supervision (2005) mentions according to the literature review and popularity in the financial industry its list of tools:

- Cumulative Accuracy Profile (CAP) and its summary index, the Accuracy Ratio (AR),
- Receiver Operating Characteristic (ROC) and its summary indices, the ROC measure and the Pietra coefficient,
- Bayesian error rate,
- Conditional entropy, Kullback-Leibler distance, and Conditional Information Entropy Ratio (CIER),
- Information value (divergence, stability index),
- Kendall's  $\tau$  and Somers' D (for shadow ratings), and
- Brier score.

This paper uses tools as Type I Error, Type II Error, ROC curve and its coefficient AuROC which are detail characterized. Measures of Type I Error and Type II Error are indispensable for models' verification. Their advantages are simple calculation not requiring difficult statistic software and easy interpretability and clearness for people without additional mathematical and statistical knowledge. It sets up bases for using Type I and II Error because almost all studies focused on the creation or verification of scoring models predicting financial distress use them. Type I Error and Type II Error are introduced in Table 1.

Tab. 1 – Type I Error and Type II Error. Source: Fernandes (2005)

		Estimated	
		Non-Default	Default
Observed	Non-Default	True	False Alarm (Type II Error)
	Default	Miss (Type I Error)	True

Type I Error occurs when a defaulted entity is classified by the models as a non-defaulted entity and Type II Error occurs when a non-defaulted entity is classified by the models as a defaulted entity. The absolute value of errors depends also on the size sample and therefore it is better to use relative measures. In the case of Type I Error the number of all defaulted entities classified as non-defaulted is divided by the number of all defaulted entities. In the case of Type II Error the number of all non-defaulted entities classified as defaulted is divided by the number of all non-defaulted entities. Models are never able to classify all entities correctly because they function only as a simplification of reality. The general consensus works on the assumption that the error of a high quality model should not exceed 20% when the error is expressed in a relative term.

Another tool is the ROC curve (Receiver Operating Characteristic) which works as a graphical tool which needs classified score of evaluated companies. The ROC curve compared with the CAP curve is more complex and it does not require the same composition of the tested sample as represented in the real world. It is a main advantage because it makes the work with models' verification easier. The ROC curve is constructed as follows. The quantities HR (C) and FAR (C) are computed for the whole range of classified scores. The ROC curve is a figure of HR (C) versus FAR (C). Further information could be found in Basel Committee on Banking Supervision (2005). The ROC is displayed by Figure 1 where the ROC curve is displayed as the Rating Model, Perfect model is a curve without any false classifications and the Random model responds to a coin flip. The index indicator ROC (also called in the literature as A, AuROC or AUC) can be presented graphically as the area under the ROC curve. The greater the area under the curve ROC is the explanatory power of the model is higher. The ROC curve is used in this paper as an additional tool.

First the models are evaluated according to Type I Error and Type II Error. After the ROC curve is displayed for models whose error rate does not exceed 20%. Type I Error and Type II Error work with original cut off points designed by models' authors. On the other hand the ROC curve does not work with original cut off points and it studies only if different cut off points are able to distinguish between defaulted and non-defaulted entities.

### 3.3 Selected industry branch

The models predicting financial distress are verified on the data sample which covers one industry branch. Companies related to different industry branches can have different performance, financial results as well as composition of assets or financial sources. These differences are omitted when companies related to the same industry are evaluated. The chosen industry branch is the construction industry. The construction industry has been heavily affected during the last economic crisis. This statement is proved by Ministry of Industry and Trade of the Czech Republic (2014) because since 2008 the construction industry has decreased annually. Researches done by Čámská (2013) or by Creditreform (Tisková informace - Vývoj insolvenčí v České republice v roce 2013, 2014) confirm that the number of defaulted entities in the construction industry is one of the highest in the Czech economy. The construction industry is generally important for the Czech economy because it has created more than 8% of annual GDP in the time period 2000 – 2010 (Czech Statistical Office, 2012).

### 3.4 Definitions of surveyed companies

The models predicting financial distress are constructed with two data samples one includes companies defined as non-defaulted (or healthy, with low risk of bankruptcy etc.) and the other one includes companies defined as defaulted (unhealthy, with high risk of bankruptcy, already bankrupt etc.). These data samples are usually used also for models' verification and therefore it is necessary to define which entities are classified as non-defaulted and defaulted.

The non-defaulted entities are defined in this paper as companies creating economic value added in years 2010, 2011 and 2012. Although the measure economic value added has its disadvantage because of the computation based on accounting values (Jordan, Westerfield and Ross, 2011) the measure economic value added can be accepted as an adequate measure of an achieving entrepreneurship goals. The achieving entrepreneurship goals is defined by Veber

and Srpová (2005) as well as by Synek and Kislingerová (2010) as the increase of the originally invested capital value.

The definition of defaulted entities is more tricky. Merton (1974) sees the default as a situation when the value of defaults exceeds the value of company. Other definitions talk about the situation when the evaluated entity does not repay its liabilities and it cannot do that. This paper works only with the data which are publicly available and therefore it is necessary to use a legal term as an insolvency proposal according to the Czech legal framework, concretely Act No. 186/2006 Coll., Bankruptcy and Settlement (the Insolvency Act). The defaulted entities are defined in this paper as companies to which the insolvency court declared the insolvency proposal. This paper works with the comparable time period and therefore the insolvency proposal had to be declared in 2012, 2013 and first months of 2014. This condition is not the only one. The second requirement is based on the availability of entities' financial statements at least three years before bankruptcy has occurred. Although all companies should publish their financial statements they do not fulfill this legal requirement (Czech Credit Bureau, 2013).

According to above mentioned criteria the entities were extracted from the corporate database Albertina. The number of entities is shown in Table 2.

Tab. 2 – Size of data sample. Source: author

	Original exported data sample Number of entities	Final data sample Number of entities
Non-defaulted	1615	237
Defaulted	172	46

## 4 RESULTS

Companies included in the final data sample are evaluated by the selected models predicting financial distress. The data sample of the non-defaulted companies is evaluated on the base of the financial statements created in the year 2012. The data sample of the defaulted companies is evaluated on the base of the financial statements created one or two years before the insolvency proposal. The z-scores are computed for all companies and after evaluated according cut off points which were suggested by their authors. Companies are divided into evaluating zones. Most models have two and three evaluating zones but there are also exceptions with more zones. Rates of Type I Error and Type II Error are computed as it is mentioned in the chapter 3.2 Research methods. The measure reliability means number of companies classified correctly divided by all companies in the related group. The sum of the rate of Type I or II Error and the measure reliability is not equal to one because some models use grey zones or some statistic units (companies) were not evaluated because some data were not available for computation.

Results of the rates Type I Error and Type II Error are included in Table 3 for all verified models except the Polish models in Table 4 for the Polish models. Errors higher than 50% and reliabilities lower than 50 % are indicated as red numbers. Orange numbers occur when the 50% boundary is almost hit.

Tab. 3 – Explaining power of the verified models except the Polish models. Source: author

Model	Defaulted entities		Non-defaulted entities	
	Reliability	Type I Error	Reliability	Type II Error
Altman	0.652	0.109	0.608	0.034
IN99	0.717	0.109	0.270	0.046
IN01	0.717	0.043	0.451	0.013
IN05	0.804	0.043	0.527	0.042
Doucha	0.370	0.304	0.456	0.139
Grünwald	0.750	0.000	0.788	0.000
Kralicek	0.848	0.022	0.502	0.110
Bonita index	0.750	0.167	0.879	0.000
Hajdu & Virág	0.109	0.891	0.970	0.025
Hajdu & Virág-logit	0.739	0.217	0.688	0.291
Šorins & Voronova	0.891	0.109	0.823	0.173
Merkevicius	0.935	0.065	0.565	0.430
2factor_1	0.087	0.913	0.975	0.021
2factor_2	0.609	0.065	0.004	0.979
2factor_3	0.043	0.652	0.992	0.004
Stoškus	0.326	0.630	0.160	0.827
Genriha & Voronova	0.261	0.739	0.979	0.017
R model	0.750	0.250	0.818	0.152

False classification in the case of defaulted entities is connected with models Holda 1, Gajdka & Stoda 1, Hajdu a& Virág, two factor model in the versions 1 and 3, Stoškus, Genriha & Voronova. Low reliability in the case of defaulted entities is connected not only with the models already mentioned but also with Doucha, Gajdka & Stoda 2, Appenzeller & Szarec, Pogodzinka & Sojak and Sojak & Stawicki. The detailed analysis using ROC curves can be applied to the models Altman, IN99, IN01, IN 05, Kralicek Quick Test, Hadasik, Holda 2, Prusak in the both versions, from the PAN family approaches C, D, E, F, G, both Wierzba models, Poznanski, D1, D2, D3, D4, Hajdu & Virág in logit version, Šorins & Voronova, Merkevicius, two factor model in the version 2, Bonita index and R model.

False classification in the case of non-defaulted entities is connected with the models D1, D4, two factor model in the version 2 and Stoškus. Also Merkevicius touches the critical number. Low reliability in the case of non-defaulted entities is connected with the models IN99, IN01, Doucha, partly Kralick Quick Test, Prusak in versions 1 and 2.

The results for the data samples of defaulted and non-defaulted companies can be sum it up that for further evaluation are appropriate the following models – Altman, IN05, Hadasik, Holda 2, from the family PAN models PAN-C, PAN-D, PAN-E, PAN-F and PAN-G, both

versions of Wierzba, Poznanski, D2, D3, Hajdu & Virág in logit version, Šorins & Voronova, Merkevicius, R model, Grünwald and Bonita index.

The models selected according results in Table 3 and 4 are evaluated by the tool of the ROC Curve and its AuROC coefficient. The ROC Curves and their AuROC coefficients are determined by the statistical program SPSS. The results are displayed in Table 5 and the models are arranged in the order from the largest area to the smallest area. All verified models fulfilled the requirement that the area should be larger than 0.5. In the case of Doucha approach the requirement is almost not fulfilled. For the other models the value of AuROC

coefficient exceeds 0.8 and their explaining power is high. They provide better results than random results as throwing the coin.

Tab. 5 – AuROC values for models with low Type I and II Error. Source: author

Grünwald	0.803	0.081	0	0.644	0.963
Doucha	0.535	0.109	0.632	0.322	0.748

The critical boundary should be higher than 0.8 because the data samples includes strictly polarized companies. If we take as the critical boundary 0.9 then the models Wierzba 2,

Prusak 2, PAN-E, PAN-F, PAN-D, IN01, IN05, IN99, Hadasik, Merkevicus, Altman, Hajdu & Virág in logit version and Grünwald have a lower discriminatory power. The questions included in the chapter 3.1 can be answered now. The question 1 was if the explanatory power of the bankruptcy models created in the past is sufficient for the decision making process nowadays. The results confirm that there are several models which have appropriate explanatory power and they can be used for the sufficient decision making process. The question 2 was which models have the highest accuracy and which should be recommended for practical use. These models are included in Table 5 and their AuROC coefficient is higher than 0.9.

## **5 DISCUSSION**

The research questions have been answered. The question 1 investigated if there are models predicting corporate financial distress with appropriate explanatory power. The research confirmed that there are plenty of models and tools which can be used for prediction financial distress and therefore they can be used for the sufficient decision making process. Specifically, the models are D3, Kralicek Quick test, PAN-G, Bonita Analysis, Poznanski model, Wierzba 1, Holda 2, R model, Prusak 1, D2, Šorins formula and PAN-C. The models do not have the same point of origin because they come from different European countries. There are German, Polish as well as Baltic approaches. The country of origin is not the necessary condition for a high quality model. These models had AuROC coefficient higher than 0.9 for the evaluated data sample. Sum it up these models were able to explain at least 90% of studied cases. The question 2 is connected with the question 1 and refers to the hypothesis if there is a need of a new predicting tool. The new predicting tool can be constructed but there is no necessity because the research confirmed that there are enough already existing models which have high accuracy for our purposes.

Although the research questions and hypotheses were answered it opens many other issues. There can exist better models than the verified models in this paper. Many models predicting financial distress were not published and plenty of them were not discovered in the literature review phase. It can be caused by different reasons as a publication of models in national languages or insignificant sources. The analysis also focused on one geographical area. The Czech Republic in the heart and foreign approaches used here supplemented by the models created in the transition economies as Poland, Hungary and Baltic states. The transition economies have the comparable political, historical and economic development as the Czech Republic and therefore they were verified.

The models predicting financial distress are usually based on the manufacturing industry data. The verified models could have different results for other industry branches than construction industry because other industry branches have different proportion of assets and sources of capital because they work on the different bases.

## **6 CONCLUSION**

This paper was focused on an explanatory power of models predicting financial distress created in the past. Dozens of models were verified in the case of construction industry which has been highly affected by the last crisis, has significant number of entities under insolvency proposal and is important for creating GDP in the Czech Republic. The paper should have answered several questions connected with models' explanatory power. Statistically significant data samples were tested by tools as Type I Error, Type II Error, ROC Curves and the related AuROC coefficients. The paper proved that there are models which have high

explanatory power and they can be recommended for the practical use. According to the results the question if there is a need of new predicting tool can be answered. There are several models as D3, Kralicek Quick test, PAN-G, Bonita index, Poznanski, Wierzba 1, Holda 2, R model, Prusak 1, D2, Šorins, PAN-C with the adequate explanatory power. It confirms that there is not the higher need of new predicting tool.

It is necessary to bear in mind that model predicting financial distress should provide quick and inexpensive answers. They can support the decision making process and they can help strategy creation but they should not be the only used approach in the evaluation of related business entities. The models generally are only a simplification of the reality and they cannot operate at 100%. The models predicting financial distress will always have some cases which are classified incorrectly. The aim is to decrease the amount of cases which are classified incorrectly.

## **AN ANALYSIS OF THE SIMILARITY OF SELECTED BANKS IN CENTRAL AND EASTERN EUROPE**

*Liběna Černohorská, Pavla Kořátková Stránská*

### **Abstract**

This paper compares analyses banks' performance in three Central and Eastern European countries (the Czech Republic, Hungary and Poland). The aim of the paper is to make a comparison of the chosen banks and bank sectors in each country based on statistic methods. We provide peer analysis on the basis of financial indicators in the chosen banks. Those indicators encompass all key groups of financial indicators (profitability, property and capital, credits, costs and revenues, liquidity and absolute indicators). First, we undertake the peer analysis through the main components and the factor analyses. Second, we provide the cluster analysis. The method of the main components and the factor analysis will be used for the first viewing the data and to investigate the similarity of chosen banks. The cluster analysis will make relatively homogenous clusters (bank groups) that will show certain similarities in chosen indicators. The algorithm of the cluster analysis follows the hierarchical agglomerative clustering. All in all, 25 banks have been selected for the analysis (8 Polish, 8 Hungarian and 9 Czech banks). Clustering was selected based on the cophenetic correlation coefficient. Cophenetic correlation coefficient selected on the basis of achieving value approaching the value of the one furthest neighbour method. Determination of the relevant number of clusters was started from the schedule clustering which identified peace distance of approximately 50%. After the cluster analysis was done, there were six clusters done plus one cluster represented by one bank, which was Equa Bank, a.s., which was similar to the last cluster. The choice of the banks was determined by banks' size in the countries of Central and Eastern Europe, because seven biggest banks of this region reside in these countries. We conclude that Czech and Polish banking sectors are stable unlike the Hungarian one, whose performance has been negatively affected by strengthening government regulation.

### **1 INTRODUCTION**

The banking system has become an important component in the economic sector of each country. Like other industries, the banking industry has its own unique characteristics and specifics that adapt by internal and external influences economic sector. Each state is required for the proper functioning of the economy needs a reliable a stable banking system, because the problems in the banking sector may have an impact on the entire financial sector. Each banking system of each country has its own specifics that influence global globalization. It operates on banking systems around the world. Each state receives it but in different ways. Some states retain more of their traditional banking features that arose during the development of the system, in turn, take some elements of the globalized economy.

Banks are an inseparable part of life for all economical subjects. The bank stability is an important assumption for function the financial markets (Teplý et al., 2010). The aim of the article is to undertake a peer analysis of chosen banks in the countries of Central and Eastern

Europe (CEE) – especially in Hungary, Poland and in the Czech Republic. The choice of the countries was determined by the biggest banks in CEE, because seven biggest banks of this region are in these countries. In the Czech Republic it is Komerční banka, ČSOB and Česká spořitelna. In Poland it is PKO Bank Polski, Banks PEKAO and mBank. In Hungary it is OTP Bank. In the Czech Republic in the end of year 2013 there were fourteen commercial banks, in Hungary there were 23 banks and in Poland there were 28 banks (without building savings banks, credit banks, specialized banks and foreign bank branches). The peer analysis allows make a comparison of the financial variables according to the tables and graphs. For this peer analysis will used the traditional methods of multiple statistical analysis, especially cluster analysis and principal components analysis. There were 25 banks chosen to do the cluster analysis (8 Polish, 8 Hungarian and 9 Czech banks).

## 2 SELECTED BANK AND FINANCIAL INDICATORS

We can use the access of the Czech National Bank (CNB) to classify the bank sector. CNB divides the banks into groups: “large banks”, “medium-sized banks”, “small banks”. As a “big bank” the CNB classes the banks with a balance sheet more than 250 billion crowns, as a “middle bank” CNB classes the banks with a balance sheet between 50 and 250 billion crowns, group of “small banks” covers banks with a balance sheet up to 50 billion crowns. A Polish central bank (Narodowy Bank Polski, NBP) and a Hungarian central bank (Magyar Nemzetu Bank, MNB) commercial bank classify the bank only as a “large banks” and “small and medium-sized banks”. (Vodová, 2013)

To be able to divide all the banks into 3 groups, there was defined a stake of the total assets of each bank (in 2013) to total assets given by the bank sectors. The banks with the stake of total assets of chosen bank sectors higher than 4 % were classified as a “large banks”. In the “medium-sized banks” group were the banks with the stake from 1 % to 4 % and in the “small banks” group were the banks with stake lower than 1 %. (This classification matches the CNB classification). The amount of banks put into each group shows the Table 1. From all groups there were randomly chosen banks from each bank sector so that banks from “small banks” group, “medium-sized banks” and “large banks” are representing. Chosen criterions were also important while choosing the banks. It is possible to say that if there are for example 5 banks of the same size and they reach the similar values in the chosen criterions, we can choose one bank as a representative for the rest of the banks. According to behaviour of the chosen bank we can assume that the rest of the banks will probably behave the same way.

Tab. 1 – Classification of “large banks”, “medium-sized banks” and “small banks” in Hungary, Poland and in the Czech Republic. Source: own calculation by Bankscope database.

	large banks	medium-sized banks	small banks
Hungary	4	3	16
Poland	6	11	11
Czech Republic	4	5	5

## **2.1 Financial indicators of bank sector**

For an entering analysis we used the data from 2013. It was possible to choose a longer term, where the missing values had been replaced by an average value. Because there were quiet big changes in the entire bank system (either in inland or abroad), we used the year 2013 for finding out the actual bonds and relations in the bank sector. It ensured us the completeness of the data of chosen banks from the view of the chosen criterions. The timing lines of chosen criterion of chosen banks could be used for a deeper analysis in following scientific research. We could see the changes of each criterions and we could point out an important moments (for example financial crisis and its influence on chosen criterions and so on).

It was necessary to choose suitable indicators for the analysis itself. While choosing the suitable indicators we need to come out of the accessibility of the banks data. There are also different accesses for financial bank indicators in the Czech literature (Babouček, 1996; Hrdý, 2005) and foreign one (Golin, 2000; Boot, 2000). The data we needed we got from the database Bankscope and they were chosen in view of the fact of specific bank sectors, international accounting standards and informative banks duty.

The financial indicators were chosen so that all groups of financial indicators were taken in consideration.

The rentability indicators cover: return on average assets (ROAA),

- return on average equity (ROAE),
- net interest margin.

The property and capital indicators cover:

- equity/total assets,
- capital adequacy.

The credit indicators cover:

- net credit/total assets

The proportion credit indicators cover:

- costs/income.

The liquidity indicators cover:

- liquid assets/total deposits.

Next there had been chosen total indicators:

- total assets
- deposits and short-term financing
- equity

## **3 THE METHODS USED**

The primary access for determining the similarity of quantitative variables is the factor analysis. It is based on principal component analysis, which is used to reduce the size of the job (instead of many variables for further calculations determined by a small number of principal components, which can be expressed as linear combinations of the original variables).

The Principal components analysis is computed by the Singular Value Decomposition of  $X$ . The general formula (1) is: (Hastie, 2013)

$$X = UDW^T \quad (1)$$

where

$D$ ...diagonal matrix consisting of the set of all eigenvalues of  $C$  along its principal diagonal, and 0 for all other elements

$U$ ...an  $n$ -by- $n$  matrix, the columns of which are orthogonal unit vectors of length  $n$  called the left singular vectors of  $X$ ;

$W$ ...a  $p$ -by- $p$  whose columns is orthogonal unit vectors of length  $p$  and called the right singular vectors of  $X$ .

In the Principal Components Analysis (PCA), the data are summarized as a linear combination of an orthonormal set of the vectors. The first principal component accounts for as much of the variability in the data as possible, and each successive component represents as much of the remaining variability as possible. (Zou, 2006) Components accounting for maximal variance are retained while other components accounting for a trivial amount of variance are not retained. These techniques are typically used to analyse groups of correlated variables representing one or more common domains. The result of PCA enters into the factor analysis. Its aim is to assess the structure and relationships of selected indicators to see if allowed by their division into groups, in which the indicators chosen from the same groups together more than correlated variables from different groups.

Cluster analysis is a collective term covering a wide variety of techniques for delineating natural groups or clusters in data sets. The article will be used hierarchical agglomerative clustering.

Hierarchical agglomerative clustering starts at the bottom and at each level recursively merges a selected pair of clusters into single clusters. This produces a grouping at the next higher level with one less cluster. Algorithm of hierarchical agglomerative clustering begins with every observation representing a singleton cluster. At each of the  $N-1$  steps the closest two (least dissimilar) clusters are merged into a single cluster, producing one less cluster at the next higher level. (Hastie, 2013)

In the first phase clustering calculates the relative distances of objects and writes them into a matrix. This leads to a square symmetric matrix  $\mathbf{D} = \{d(R, S)\}$  which has zeros on the main diagonal. It is used for calculating the metric distance matrix is normally used and it is called a Euclidean method. It is based on the geometric model. (Klímek, 2005) The objects characterized by  $p$  characters are assigned to the points  $p$ -dimensional Euclidean space  $E_p$ , then two dots  $(R, S)$  it is defined by the Euclidean distance given by general formula (2):

$$d(R, S) = \sqrt{\sum_{i=1}^p (x_{ri} - x_{si})^2} . \quad (2)$$

On the basis of the distance matrix can be launched the second phase calculations, also clustering. Clustering method was used furthest neighbour (called too complete linkage). Complete linkage agglomerative clustering takes the intergroup dissimilarity to be that of the furthest (most dissimilar) pair according to formula (3):

$$d(R, S) = \max_{\substack{O_i \in R \\ O_j \in S}} \{d(O_i, O_j)\} \text{ for } R \neq S \quad (3)$$

where

$R, S$  ...represent two such groups

$d(R, S)$  ...represent dissimilarity between  $R$  and  $S$  in computed from the set of pairwise observation dissimilarities  $d(O_i, O_j)$ , where one member of the pair  $O_i$  is in  $R$ , and the other  $O_j$  is in  $S$ .

Methods of clustering is selected based on the degree of credibility, and it cophenetic correlation coefficient "CC". The higher the value of the correlation coefficient cophenetic (a value close to 1), the greater the credibility and the choice of a suitable model cluster. (Hastie, 2013; Hebák, 2007; Lavine, 2000; Meloun, 2005; Romesburg, 2004)

The result is graphical figure called a dendrogram with provided a highly interpretable complete description of the hierarchical agglomerative clustering.

## 4 ANALYSIS OF SELECTED BANK

### 4.1 Visualization of date using factor analysis

We use the method of principal components and factor analysis for graphical visualization prior to the cluster analysis. (Hastie, 2013; Hebák, 2007; Meloun, 2005)

The first principal component depletes approximately 34.71% of the total variability in the data, the second approximately 22.66 %. The results of the factor analysis bring Tab. 2 and Fig. 1. Tab. 2 shows which criteria are important for further exploration in terms of classification into certain objects, respectively clusters (bold face type).

Tab. 2 – The result of the factor analysis – the first two principal components. Source: own calculation by Bankscope database.

	<b>First principal component 1</b>	<b>Second principal component 2</b>
Net interest margin	-0.103488	<b>0.706424</b>
Net credit/total assets	0.114454	<b>0.858046</b>
Costs/revenues	-0.519822	-0.138174
Capital adequacy	-0.537590	0.232883
Equity/total assets	-0.113775	0.659776
Return on average assets (ROAA)	0.521883	0.101157
Return on average equity (ROAE)	0.689154	0.264687
Liquid assets/total deposits	-0.611671	-0.196073

Total assets	<b>0.924784</b>	-0.05947
Deposits and short-term financing	<b>0.922965</b>	-0.010474
Equity	<b>0.899850</b>	0.100069

Allocation of selected banks according to two principal components showed Fig. 1. From the visualization can make a judgment about what banks are similar in defined criteria and therefore on the basis of similarity in all selected request one cluster.

## **4.2 Result of cluster analysis**

The basic condition for performing cluster analysis is rejected claim that the data are affected by multicollinearity. Multicollinearity could very significantly affect the final quality of the clustering and classification of the individual elements in the resulting clusters. It is necessary to establish the correlation matrix. Then eliminate those criteria in assessing the relationship reaching the correlation coefficient higher than 0.7. If left criterion which the correlation coefficient is above 0.7. It is necessary to provide a justification for its further occurrence of cluster analysis.

The presumption was verified using the Spearman correlation coefficient, in our case. Criteria which enter the cluster analysis and multicollinearity meet the condition are:

- net interest margin,
- net credit/total assets,
- costs/revenues,
- capital adequacy,
- equity/total assets,
- return on average assets (ROAA),
- equity.

The following two criteria were multicollinearity affected. To the fact that the correlation coefficient value slightly exceeds the recommended limit of 0.7 (in excess is 10%) and are important criteria. Then still be included in the analysis:

- total assets,
- deposits and short-term financing.

This is followed by a selection of clustering procedures and methods of clustering (furthest neighbours method. resp. Complete the connection using statistical Statistica version 12.1) and the method of calculation of distances (Euclidean distance). Clustering was selected based on the cophenetic correlation coefficient. Cophenetic correlation coefficient selected on the basis of achieving value approaching the value of the one furthest neighbour method.

Determination of the relevant number of clusters was started from the schedule clustering which identified peace distance of approximately 50%. Below this level determine the relevant number of clusters (See Fig. 2).

Fig. 2 – Dendrogram. Source: own calculation.

After the cluster analysis was done, there were six clusters done + one cluster represented by one bank, which was Equa Bank, a.s., which was similar to the last cluster (from the bottom).

The first cluster (in the bottom part of dendrogram) is internally divided into two clusters (See Fig. 2). In the first cluster there are two polish banks (PKO Bank SA and Bank Pekao SA), in the second cluster there is one polish bank (mBank SA) together with two Czech banks (ČSOB and ČS). All those banks come from the group of “large banks”, no Hungarian bank from this group is here. Characteristic feature for this cluster is a high value of criterions total assets (average value in this cluster is about EUR 35 732 billion), deposits and short-time financing (average level of this criterion is about 28 529 billion EUR) and the level of own equity (average value of this cluster is about 4 135 billion EUR). The average value of this indicator ROAA for the first cluster is about 1.7 %, which can be considered as a satisfying situation (Tab. 3). The ROAA indicator measures assets payback, which means how much profit can banks generate from available assets. The advantage of this indicator is that it can be measured among the banks in different economic environment and it is not influenced by banks debts. If the level of ROAA indicator is lower than 0.75, it is a weak assets payback. If the level of ROAA indicator is higher than 1, the assets payback is excellent. Recommended value of this indicator is 1.

Second cluster is constituted by one Czech bank (Sberbank CZ), two polish banks (Getin Noble Bank SA, Alior Bank Spólka Akcyjna) and two Hungarian banks (K&H Bank Zrt, Unicredit Bank Hungary). One other Hungarian bank CIB Bank Ltd joined this cluster – CIB Bank is similar to other banks in this group, but in ROAA indicator achieves extreme values (as the only one it achieves even negative values). Only two banks achieve the recommended values (Alior Bank and UniCredit Bank Hungary). The CIB Bank’s negative ROAA value is caused by deterioration assets 'quality of Hungarian banks as a result of a higher credits' stake

after maturity more than 90 days and making higher capital reserves in these banks. The sixth clusters show same low values of ROAA. Two Hungarian banks are in this sixth cluster.

The third cluster formed four banks: one Czech bank (Evropsko-ruská banka), two polish banks (Dominet Banks SA, Bank Pocztowy) and one Hungarian bank. This cluster showed a high level of net interest margin. There were some changes of interest-bearing assets of bank sheets, which caused the high level of this indicator.

The fourth cluster was formed by two Czech banks (Fio Bank and PPF Bank), one polish bank (FM Bank PBP) and one Hungarian bank (Citibank Zrt). Characteristic feature of this cluster was a low value of net credit indicator/total assets in the level of not even 33 %. Bank should set a maximal level of this stake, so that there are no problems with liquidity. According to a low level of this indicator banks in this cluster do not have any problems with liquidity. The average value of this indicator in other cluster is about 60 %, the fifth cluster achieves even higher values (75 %).

The fifth cluster is formed only by one Czech bank (GE Money Bank) and one Hungarian bank (Evobank Zrt). In case of net interest margin indicator this cluster shows extremely high values. It was caused by a decrease of the short-term deposits from clients from public and financial sector.

The sixth cluster is formed by two Hungarian banks (DRB Dél-Dunátúli, Szécheney Kereskedel). Just like the second cluster, the sixth cluster has extremely low values of ROAA indicator. According to negative values of this indicator it is showed that these banks, that were mentioned, have a very low rentability of their assets. The causes of a low ROAA values are explained in the second cluster. Compared to other formed cluster there is also an extremely low value of total assets and deposits.

Tab. 3 – Average values of chosen indicators. Source: own calculation by Bankscope database.

	cluster						
	first	second	third	fourth	fifth	sixth	Equa Bank
<b>Net interest margin</b> [in % ]	3.3	2.9	6.2	2.2	7.37	3.38	1.3
<b>Net credit/Total assets</b> [in % ]	61	67.7	60.3	32.82	75.28	57.69	62.4
<b>Costs/Revenues</b> [in % ]	44	51.5	94.6	69.3	61.59	70.45	1 677.5
<b>Capital adequacy</b> [in % ]	16.1	13.4	12.8	10.9	10.2	11.6	22.6
<b>Equity/Total assets</b> [in % ]	11.4	9.2	9.7	9.8	35.29	8.65	14.42
<b>ROAA</b> [in % ]	1.7	-0.26	0.1	2.5	2.25	-4.19	-5.9
<b>Total assets</b> [in EUR]	35 732	7312	1346.1	1173.8	2721.16	95.77	357.4
<b>Deposits and short-term financing</b> [in EUR]	28 529	5983	1125.1	931.4	1946.84	85.60	298.4
<b>Equity</b> [in EUR]	4 135	659	150.1	97.2	698.00	7.97	51.5

The Equa Bank was separated and formed an individual cluster. It is a new bank working on a Czech market (since 2011) and that is why we can assume improvement of ROAA indicator in the future. In June 2012 it was planned to increase the capital with 753.6 billion crowns, which confirms a long-term interest of stakeholders to equity the bank with an adequate capital, so that the bank can have an ambitious commercial growth. In the first half of the same year there was a 171 % year-to-year growth of credit volume up to 8.4 billion crowns. The clients' deposits grew with 96 % in the first half of the year up to 10.5 billion crowns. (Equa bank, 2013) These facts influenced the extremely high level of the cost/revenues indicator.

From the view of the stability of bank sectors, the indicator of capital adequacy BASEL II is very important. Any of the observed banks, where was this indicator showed, did not have the capital adequacy lower than asked 8 %. In the present no banks from observed bank sectors have the problem with the asked height of the capital.

### **4.3 Discussion and summary analysis**

On the basis of found results we can say that banks associated within the size classification to "large banks", "medium-sized banks" and "small banks" (ČNB, 2003 - 2014). The Hungarian banks are exception, because they are dealing with specific problems that neither Czech nor polish sector does not have to deal with (Vodová, 2013; Dec and Masiukiweicz, 2011). Into the first cluster the "large banks" from Czech and polish bank sector were involved. According to an origin plan we can judge that also the rest of the "large banks" in observed bank sector will behave the same way.

The second cluster involved all "medium-sized banks" from Czech and polish bank sector. One big and one middle bank from Hungarian bank sector are involved here as well. The incorporation of the "big" Hungarian bank (K&H Bank Zrt) into this group is caused by not such high stake of assets to total assets of the Hungarian bank sector (in case of K&H Bank Zrt the stake is 4.44 % while the stake of ČSOB's assets to total assets of Czech bank sector is 19.6 %, the stake of Česká spořitelna is 19.3 % and in Poland PKO BP has a 13 % stake on assets of the polish bank sector. Polish bank Pekao has 10 % stake).

The third cluster formed banks belonging to a "small banks" group. Their stake on assets of relevant bank sectors is between 0.05 % and 0.6 %. The fourth cluster covers banks from "medium-sized banks" as well as "small banks" groups. The fifth cluster is made by a Czech bank with the assets' stake 2.6 % to total assets from the Czech bank sector. Hungarian bank has the stake to total assets of a Hungarian bank sector only 0.03 %. This may be evidence of the negative impact of banking reforms and the fear of losing political independence of Hungary CB on the Hungarian banking sector. This may be evidence of the negative impact of banking reforms and the fear of losing political independence of Central Bank of Hungary on the Hungarian banking sector. (The Economist, 2013)

In the sixth cluster there are only two "small" Hungarian banks. One "small" Czech bank seems to be joining this cluster, but this bank works on a Czech market only for two years and according to dynamic development we can assume, that in the future it would join another cluster.

The results of the analysis can be stated that among the other bank is a group of Hungarian banks and Equa bank. Hungarian banks are faced with the specific situation on the financial market (The Economist, 2013). Equa bank is operating on the Czech banking market from 2011. The new established banks have different values of financial indicators in a comparison with banks operating on the market longer. Newly established banks tend to concentrate on

getting a large number of clients. The same conclusion see also in Jemric, I., Vujcic, B. (2002) or Turnbull, P. W., Gibbs, M. L. (1987).

If a new bank would appear on the bank market (newly arise, transformation from different law form such as credit unions) with the values of criterions similar to some cluster in set average values of criterions, we can suppose that the bank would very likely join that cluster. It would not be necessary to make a new analysis. This research problem (joining newly arise banks into bank system) asks for a deeper investigation to support this argument.

## 5 CONCLUSION

Observed bank sectors in CEE are currently stable based on our analysis, any of the observed banks did not show negative values of chosen indicators. All the legislative measures in European Union have been harmonized (Kalemli-Ozcan, S. et al., 2010). All banks need to comply with the rules of national regulators that contribute to smooth functioning of the bank industry in CEE. The bank privatization and enter of external owners played an important part for each bank sector in the past years (Koutsomanilo-Filippaki, A. et al., 2009). Thanks to that the competitive ability of transitive economic within the global financial markets was available. The only different evinces the Hungarian bank sector that remains unprofitable since 2010 mainly because of implementation of bank tax (Dec and Maiukiewicz, 2011). However, the government of Hungary tries to solve the recovery from public finances this way. In 2013 the tax from financial transactions was imposed. All of this can lead to decreasing support from local branches from foreign parent banks in Hungary (The Economist, 2013).

## **STOCK-MARKET EFFICIENCY IN EMERGING MARKETS: EVIDIENCE FROM VIETNAMESE STOCK MARKET**

*Do Thi Thanh Nhan, Le Tuan Bach, Nguyen Thanh Trung*

### **Abstract**

The objective of this study is to find out whether the Vietnamese stock market is weak-form efficient. This paper applies data daily and weekly returns of VN-index and HNX-index in Hochiminh and Hanoi Stock Exchange, respectively from 2000 to 2013. The results obtained from the test indicate significant deviations from the random walk hypothesis of the stock returns in the Vietnamese market, in which the majority of data experience is positive correlations. Furthermore, the nonparametric runs test is used to determine the randomness of a price or a return sequence as an alternative. The test once again confirms that the Vietnamese stock market is not weak-form efficient.

### **1 INTRODUCTION**

The Efficient Market Hypothesis (EMH) is one of the most controversial and well-studied proposition in economic and financial theories. According to Fama (1965, pp. 3-4), "An 'efficient' market is defined as a market where there are large numbers of rational, profit-maximizers actively competing, with each trying to predict future market values of individual securities where important current information is almost freely available to all participants. In an efficient market, competition among the many intelligent participants leads to a situation where, at any point in time, actual prices of individual securities already reflect the effects of information based both on events that have already occurred and on events which, as of now, the market expects to take place in the future. In other words, in an efficient market at any point in time the actual price of a security will be a good estimate of its intrinsic value." Fama (1970) synthesizes the existing work and classifies market efficiency into three different forms. The information set is categorized into three subsets depending on the degree of information available.

While tests of semi-strong form and strong form market efficiency are rare, weak-form tests are numerous. The evidence obtained from developed markets (Cheung et al., 2001; Worthington et al., 2004; Kima et al., 2008; etc.) suggests that stock markets in these countries are efficient at least in the weak form. Some stock markets in emerging and developing countries do not exhibit weak-form efficiency whereas others show the inverse. However, as the market is in an early stage and is still developing, market efficiency can change over time as the market evolves. An evidence of weak-form efficient market can affect current strategies of the majority of investors relying on technical analysis in the market. More importantly, on March 1, 2012, the government issued the Decision No. 252-QD-TTg specifying the strategy for the market development for the period 2011-2020, in which the information efficiency is one of requirements toward achieving a developed stock market. Therefore, an updated research is essential to determine the efficiency of the Vietnamese stock market.

## **2 REVIEW OF RELEVANT THEORIES AND EMPIRICAL STUDIES**

The weak form of EMH is the lowest level of efficiency that defines a market in which stock price reflect market trading data including past prices and trading volume. If a market is weak-form efficient, there is no correlation between successive prices, so that excess returns cannot consistently be achieved through the study of past price movements. Therefore, tests of weak-form EMH are usually based on the examination of the relationship between current and past prices.

Regarding developed markets, Worthington and Higgs (2004) examined 16 developed markets from 1987 to 2003 using autocorrelation test, runs test, unit root test and variance ratio test. The result could not reject the random walk hypothesis in the majority of developed markets. Worthington and Higgs (2006) continued to conduct a study to test the weak form market efficiency of five developed stock markets (Australia, Hong Kong, Japan, New Zealand and Singapore). The serial correlation and runs tests concluded that all of the markets were weak-form inefficient, while only the developed markets in Hong Kong, New Zealand and Japan were weak-form efficient according to the variance ratio test. Nisar and Hanif (2012) tested weak form market efficient on developed markets of North America and Europe. The results of runs test and multiple variance ratio tests concluded that two out of six developed stock markets tested did not follow random walk, which meant the remaining NYSE Composite, S&P/TSX Composite, DAX 30 (Germany) and IBEX 35 (Spain) were weak form efficient markets.

Regarding developing markets, Dickinson and Muragu (1994) used the autocorrelation test together with the runs test on weekly price series of 30 individual stocks listed on the Nairobi Stock Exchange for the period of 1979-1989. Moreover, Dickinson and Muragu found that the majority of individual stock price series satisfied the conditions of weak-form EMH. Urrutia (1995) applied the runs test and variance ratio test on monthly data for market indexes in Argentina, Brazil, Chile and Mexico for the period from December 1975 to March 1991. The findings from the runs test could not reject the hypothesis for these markets. Karemera et al. (1999) investigated monthly stock market indexes for 15 emerging stock markets and found Brazil, Hong Kong, Indonesia, Jordan, Korea, Malaysia, Mexico, Thailand and Turkey markets to be weak-form efficient using the runs test. Olowe (1999) applied the autocorrelation test to monthly returns data of 59 individual stocks listed on the Nigerian Stock Market over the period 1981-1992 and failed to reject the null hypothesis of weak-form market efficiency for the Nigerian Stock Market. Mobarek et al. (2000) studied the efficiency of the Bangladesh Security on the Dhaka Stock Exchange by using the autocorrelation and run test for the 1988-1997 period and concluded that the returns of Dhaka stock market did not follow random walks. Abeysekera (2001) indicated that the Colombo Stock Exchange (CSE) in Sri Lanka was weak form inefficient by using the autocorrelation test, runs test and unit root test for the period from 1991 to 1996. The findings of these tests consistently rejected the random walk hypothesis. Wheeler et al. (2002) examined the daily returns series of 16 individual stocks listed on the Warsaw Stock Exchange from 1991 to 1996. The test result failed to support the null hypothesis of weak form of market efficiency for most of the individual stocks. Moustafa (2004) examined stock prices in United Arab Emirate stock market using the runs test. The daily data of 43 stocks for the period from 2001 to 2003 resulted in 40 stocks out of the 43 being random. Thus, this supported the weak-form market efficiency of United Arab Emirate stock market.

A summary of yearly sorted empirical studies is given in the table below.

**Tab. 1 - Summary Of Empirical Studies On Testing Weak-Form EMH**

<b>STUDY</b>	<b>METHODOLOGY</b>	<b>DATA</b>	<b>FINDINGS</b>
Dickinson and Muragu (1994)	- Autocorrelation test - Runs test	Weekly price series of 30 individual stocks listed on the Nairobi Stock Exchange for the period of 1979-1989	The majority of individual stock price series satisfy the conditions of weak-form EMH.
Urrutia (1995)	- Runs test - Variance ratio test	Monthly data for market indexes in Argentina, Brazil, Chile and Mexico for the period from Dec 1975 to Mar 1991	The results can't reject the hypothesis for these markets.
Karemera et al. (1999)	- Variance ratio test - Runs test	Monthly stock market indexes for 15 emerging stock markets (Argentina, Brazil, Chile, Hong Kong, Indonesia, Israel, Jordan, Korea, Malaysia, Mexico, Philippines, Singapore, Taiwan, Thailand and Turkey) during the period from Dec 1987 to May 1997 (11 markets) and from Jan 1986 to Apr 1995 (4 markets)	Brazil, Hong Kong, Indonesia, Jordan, Korea, Malaysia, Mexico, Thailand and Turkey markets are weak-form efficient.
Olowe (1999)	- Autocorrelation test	Monthly returns data of 59 individual stocks listed on the Nigerian Stock Market over the period of 1981-1992	The test fails to reject the null hypothesis of weak-form market efficiency for the Nigerian Stock Market.
Mobarek et al. (2000)	- Autocorrelation test - Runs test	The Bangladesh Security on the Dhaka Stock Exchange for the period of 1988 to 1997	The returns of Dhaka stock market do not follow random walks.
Abeysekera (2001)	- Autocorrelation test - Runs test - Unit root test	Colombo Stock Exchange (CSE) in Sri Lanka for the period from 1991 to 1996	The findings of these tests reject the random walk hypothesis.
Wheeler et al. (2002)	- Autocorrelation test - Runs test	Daily returns series of 16 individual stocks listed on the Warsaw Stock Exchange from 1991 to 1996	The result rejects the null hypothesis of weak form of market efficiency for most of the individual stocks.
Moustafa (2004)	- Runs test	The daily data of 43 stocks on United Arab Emirate stock market for the period from 2001 to 2003	The test results in 40 stocks being random. Thus, this supports weak-form market efficiency.
Worthington et al. (2004)	- Autocorrelation test - Runs test - Unit root test - Variance ratio test	Sixteen developed markets from 1987 to 2003	The result cannot reject the random walk hypothesis in the majority of developed markets.
Worthington et al. (2006)	- Augmented Dickey-Fuller test - Autocorrelation test - Phillips-Perron test - Runs test - Unit root test - Variance ratio test	Five developed stock markets (Australia, Hong Kong, Japan, New Zealand and Singapore) and ten emerging stock markets in Asia (China, India, Indonesia, Korea, Malaysia, Pakistan, the Philippines, Sri Lanka, Taiwan and Thailand) up to May 28, 2003	The serial correlation and runs tests conclude that these markets are weak-form inefficient. While Hong Kong, New Zealand and Japan are weak-form efficient according to the variance ratio test.
Loc et al. (2010)	- Autocorrelation test - Runs test - Variance ratio test	Daily and weekly price series of VN-Index and REE, SAM, HAP, TMS and LAF27 from Jul 28, 2000 to Dec 31, 2004	In general, the study concludes that the Vietnamese stock market is weak-form inefficient.
Vinh et al. (2010)	- Autocorrelation test - Runs test - Variance ratio test - Regression test	Daily and weekly price series of VN-Index and 8 individual stocks (CII, ITA, SJS, TDH, ABT, AGF, TS4, FMC) from	The results from all tests fail to support the hypothesis of weak form efficiency with the daily data. However, with

-	ARCH, GARCH (1,1)	2007 to 2010	weekly data, the results obtained from runs test and autocorrelation test do not completely reject the hypothesis of weak form efficiency.
Nisar and Hanif (2012)	- Runs test - Variance ratio test	Monthly, weekly and daily data of NYSE Composite (USA), S&P TSX Composite (Canada), FTSE 100 Index (UK), CAC 40 (France), DAX 30 (Germany) and IBEX 35 (Spain) for the period from Jul 1997 to Jun 2011	NYSE Composite, S&P/TSX Composite, DAX 30 and IBEX 35 are weak form efficient markets.

### 3 METHODOLOGY

As previous empirical studies, portmanteau test and run test have been the two most widely used methods for investigating the weak form of EMH.

Portmanteau test was derived from the autocorrelation test. Serial correlation, also referred to as autocorrelation in the context of stock market, refers to the tendency for future stock returns to be related to past returns. The test aims at determining whether serial correlation of returns is significantly different than zero or not. If all the serial correlations of returns are statistically equal to zero, returns are independent and prices are random. Otherwise, a positive correlation indicates that a positive (negative) return tends to be followed by a positive (negative) return; and a negative correlation means that a positive (negative) return tends to be followed by a negative (positive) return.

In order to examine serial dependence in stock price changes, researchers have employed different tests to measure their autocorrelations and test whether several autocorrelations of stock returns are simultaneously equal to zero. Such a test, often referred to as Q statistic (Q test), was given by Box and Pierce (1970) who proposed the Portmanteau statistic. Ljung and Box (1978) modified the Q statistic to increase the power of the test in finite samples. Two test hypotheses are

$$H_0: \rho_1 = \rho_2 = \dots = \rho_k = 0,$$

$$H_1: \rho_j \neq 0 \text{ for some } j \in \{1, \dots, k\}$$

where  $\rho_j$  is the  $j^{\text{th}}$  autocorrelation.

## 4 EMPIRICAL RESULTS

### 4.1 Data and descriptive statistics

The data used in this research is the daily closing prices of VN-Index during the period from August 2, 2000 to December 31, 2013 and of HNX-Index during the period from January 4, 2006 to December 31, 2013, together with individual stock prices listed on VN-Index that are available up to December 31, 2013. The data is obtained from the adjusted prices of Hochiminh and Hanoi stock exchange.

From the daily data, weekly prices are extracted. The weekly return series are calculated based on the closing value for Wednesday of each week. If Wednesday value is missing, then

the Tuesday closing price (or Thursday if Tuesday price is also missing) is used instead. In the event that Tuesday, Thursday and Wednesday closing prices are missing, the return for that week is reported as “missing value”. The choice of Wednesday values is suggested by Huber (1997) in an attempt to eliminate the weekend effect, which refers to the tendency of stocks to exhibit relatively large returns on Fridays compared to those on Mondays, and to minimize the number of holidays. The returns are computed as continuously compounded returns.

According to Campbell, Lo and MacKinlay (1997), the purpose of the computation of stock returns using natural logarithm is to stabilize the variance of the price series over time and incorporate their exponential growth behavior.

The values of some main descriptive statistics, including mean, median, maximum, minimum values, standard deviation, measures of skewness and kurtosis of VN-Index and HNX-Index are provided by Stata 12 in Table 1.

Both the means of daily and weekly data, as well as the median of weekly data, are positive, suggesting that VN-Index is expected to increase over time. The parameters skewness and kurtosis are, respectively, the measures of asymmetry and the degree of peak of the probability distributions of the returns. They are used to indicate whether a data set is normally distributed or not. For normal distribution data, the value of skewness and kurtosis are zero and three respectively. Given the value of skewness and kurtosis of the data, it is indicated that both daily and weekly return distributions are characterized as negatively skewed (long left tail) and leptokurtic (having a more acute peak around the mean and fatter tails).

On the other hand, HNX-Index experiences negative means and medians for both daily and weekly data, implying that HNX-Index is expected to decrease over time. The value of skewness and kurtosis indicates that both daily and weekly return distributions are characterized as positively skewed (long right tail) and leptokurtic (having a more acute peak around the mean and fatter tails).

## **4.2 Test results**

- ***Portmanteau test***

For testing the weak-form EMH, the Ljung-Box test is conducted first. If autocorrelation coefficients are significant in the results, stock prices are predictable as future prices can be derived from past prices. Thus, investors can make abnormal profits by establishing a trading strategy on the basis of past information.

The results are shown in Table 2 and Table 3. Regarding VN-Index, the Ljung-Box Q statistics of daily and weekly data reported for eight lags are all significant at 1% level (p-value are all equal to zero). Hence, the null hypothesis of no autocorrelation in the data is rejected, suggesting that autocorrelations exist in both daily and weekly return series of VN-Index. It is worth nothing that there is a presence of positive sign of the autocorrelation coefficients. This indicates that consecutive returns tend to have the same sign, so that a positive (negative) return in the current day tends to be followed by an increase (decrease) of return in the next several days. Such positive autocorrelations tend to exist if the market adjusts slowly to information.

Regarding HNX-Index, the p-values of daily data are close to zero for all lags, implying that the null hypothesis is rejected at 1% level. However, the weekly data shows slightly different results. The null hypothesis is rejected at 5% level for the 1st lag of weekly return, while the 2nd lag result fails to reject the null hypothesis even at 5% level. However, all the results for the 3rd, 4th, 5th, 6th, 7th and 8th lags show that there are correlations at 1% level. Again, the

results for autocorrelation coefficients for HNX-Index are mixed. For daily data, there are positive autocorrelation for all lags except for 6th and 7th lags. For weekly data, only 5th and 8th lags experience negative autocorrelation. This indicates that prices on HNX-Index tend to revert to the mean faster than VN-Index, which still has positive correlation after eight lags.

As Hochiminh stock exchange is currently accounting for 85% of total market capitalization of Vietnamese stock market, it is worth expanding the investigation into the data of 327 stocks listed on the HOSE up to December 31st, 2013. Using the Ljung-Box test daily returns, we obtain the results in Table 4 below.

The results indicate that the majority of stocks show a strong degree of autocorrelation for all the period of lags at 5% significant level.

At 1% significant level, the same is true for the 1st and 2nd lags. However, the stocks that have the highest degree of autocorrelation for the 1st lag are BMC, VIS, VHG, SJS and MCV. All of these stock experience significant positive autocorrelation for the 1st lag. On the other hand, the stocks that show the lowest degree of autocorrelation for the 1st lag are APC, C32, TBC, AGD and ELC. It is also observed that most of the autocorrelation coefficients for the 8<sup>th</sup> lag are positive, implying that prices of one stock tend to move in the same direction up to the 8-day period. The results from testing consolidate the null hypothesis of no autocorrelation of returns, indicating the inefficiency in the Vietnamese stock market.

- ***Runs test***

To test for the weak-form efficiency of the Vietnamese stock market, the nonparametric runs test is also used in this study. The runs test is considered more appropriate than the parametric autocorrelation test since all observed series do not follow the normal distribution.

Results of the runs tests for daily and weekly returns of the indexes are summarized in Table 5. The table shows that the actual number of runs in all the daily data is significantly smaller than the expected value, even at 1% level. This means the null hypothesis is rejected for the daily data. The negative Z-statistic values also indicate a positive serial correlation in the price series.

For the weekly observed returns, the results also indicate that the null hypothesis of independence among stock returns is rejected for both market indexes. Again, positive serial correlation is observed for the weekly data, which is similar to the results of daily returns.

In general, the runs test provides evidence to strongly reject the null hypothesis of random walk for both daily and weekly observed returns of the indexes. This result is similar to the findings in the autocorrelation test.

## **5 DISCUSSION**

The results are rather consistent with previous studies of Loc et al. (2010) and Vinh et al. (2010) whereby they strongly rejected the weak-form EMH of the Vietnamese stock market. The rejection of weak-form EMH indicates that daily and weekly stock prices do follow a trend. Therefore, it is possible to study this trend and predict the stock prices to generate abnormal returns.

In particular, most of the stocks showing the highest level of autocorrelation are in construction and mining industries which have seen stagnant growth in the past few years due to economic conditions. This suggests that it is possible to achieve abnormal returns using technical analysis on these stocks. On the other hand, stocks with lowest degree of autocorrelation belong to agriculture, fishery, technology and energy industries which are key industries for the national economic development and should be expected to exhibit rapid

development in the future. It is realized that chartists would find it difficult to make money from these stocks' patterns.

Furthermore, the results of the Ljung-Box test of individual stocks suggest that the more the market attracts investors, the more the efficiency of the market. One possible explanation is that investors are hesitant to maintain their active trading in these stocks, delaying the process of price adjustments to information. Chartists have a chance to draw their patterns and profit from them.

## **6 CONCLUSION**

The Efficient Market Hypothesis is one of the most controversial and well-studied proposition in economic and financial theories. Throughout the history of the literature, the different levels of efficiency of various markets have long been of great interest to researchers. In developed markets, there are many studies showing support of weak-form efficiency. However, the results for emerging markets are mixed. Vietnam is considered a developing country and stock market possesses many characteristics found in most developing and emerging stock market around the world.

The results obtained from the portmanteau test indicate significant positive autocorrelation coefficients of the stock returns in the Vietnamese market. Further examination of 327 individual stock data up to Dec 31, 2013 yields the similar results, with the majority of data experiencing significant positive correlations. Also, nonparametric runs test once again confirms the existence of positive correlations in the data, hence, rejects the weak-form Efficient Market Hypothesis. The implication of these results is that the Vietnamese stock market is still not weak-form efficient.

## **LIFE INSURANCE AND THE ROLE OF FINANCIAL ARBITRATOR FOR THE RESOLUTION OF DISPUTES WITHIN LIFE INSURANCE**

*Eva Ducháčková, Otakar Schlossberger*

### **Abstract**

Life insurance is a standard tool of the insurance market. Its role, significance and form are changing throughout its development in relation to changing conditions of life insurance. It is characteristic for the recent period that life insurance has been going through modifications, in particular the typical increase in the share of unit linked life insurance. Life insurance and especially unit linked life insurance have been recently facing a few challenges. Some of them resulted from changing financial markets and others were connected with the conclusion of life insurance policies. Effective solutions to those issues are being searched for, among others via the Financial Arbitrator Office. This essay aims to analyse current problems related to life insurance, to indicate possible solutions and to specifically point out the chances of asking the Financial Arbitrator Office to deal with possible disputes within life insurance.

The paper has been prepared under GAČR project entitled “Post-crisis banking regulation and its impact on the economic activity within a small, export-oriented economy”, under reference number 13-08549S, with the University of Finance and Administration (VŠFS) as the grant beneficiary and research project of the Faculty of Finance and Accounting at the University of Economics, Prague, Institutional support of the University (IP 100040).

*Keywords: life insurance, unit linked life insurance, technical provision of life insurance, risk portion of premium, investment portion of premium, financial arbitrator*

JEL Classification: G22, G28

### **1 INTRODUCTION**

Life insurance is intended for life natural events, i.e. demise and the rest of one's life. Its content and concept have been changing throughout its development. The original form connected with covering risks of the family breadwinner's demise and the consequences for the family members has been extended to cover additional risks affecting people's lives, such as injuries, invalidity, illness etc. by the savings portion (rest of one's life). Besides the standard approach to create the technical provision of life insurance, its investment form has recently been developed into the so-called unit linked life insurance. In the true sense of the word, it is a combination of life insurance and investments in shares funds. As a result, in some countries the unit linked life insurance is not included in the insurance products but in investment products (especially in cases where the risk portion of premium is minimal and where it refers to insurance with lump-sum paid insurance premium). In connection with the application of the unit linked life insurance, we observe discrepancies and disputes between insurance companies and the insured. The beneficiary of life insurance is a citizen as the user. Since 2013, the extrajudicial dispute settlement body - the Financial Arbitrator of the Czech Republic has been entitled to deal with disputes between insurance companies and their clients within the life insurance area.

## **2 OBJECTIVE AND METHODS**

The aim of the paper is to analyze the current problems in the area of life insurance, to show the possibilities of their solution and then to specifically demonstrate the possibility to use the financial arbiter authority for solving any disputes arising out of life insurance business. The authors consider by the processing of given theme the following question: It is possible within using the analyzed indicators and implementation the institutions for consumer protection in the financial market (in particular the Financial Arbiter) to contribute to higher transparency of the life insurance and eliminate some of the problems associated with the operation of life insurance (Daňhel, Ducháčková, Radová, 2008, p. 604).

In processing the contribution were used the methods of description, deduction and analytic comparisons.

## **3 THEORETICAL BASIS**

The significance of life insurance has been changing throughout its development, extending its scope from its original main focus to covering the demise risk and the current broad concept. At present, we can define basic areas of life insurance:

- Risk coverage: mainly demise risk to provide for the bereaved or as a tool to cover a loan, and these days in addition to the demise risk the life insurance usually includes the coverage of additional related risks, such as injuries, severe illness, invalidity etc.,
- Savings for old age: the savings portion in life insurance represents production of savings for the old age,
- Investment tool, for the life insurance represents savings with yield, the form and amount of which is modified following a specific type of life insurance,
- From today's macro-economic point of view, life insurance represents a tool to cover needs of people in old age as an alternative to social pension scheme and it is necessary to stress the counter-inflationary effect of life insurance – deferred consumption and savings production by the insured persons in reserves which in connection with investments of insurance companies allow funding of medium- and long-term investments.

In the conditions of ageing population, thus increasing obligations in the area of elderly care, there is growing significance of life insurance as a tool to cover these financial needs. Life insurance in developed countries becomes an integral part of the whole pension scheme system – it represents optional extra protection. Moreover, unlike the obligatory public scheme it is far more flexible in terms of the sum, frequency and methods of contribution payments, (or rather the insurance premium) or to the contrary the payment of insurance benefits (or rather indemnity). Life insurance thus allows people to split the financial flows in the course of the whole life span according to their individual needs and not to rely only on how the state is going to take care of them.

The role played by life insurance when ensuring financial means for the old age is increasingly stronger and more distinct, gradually expanding its traditional function as protection in case of sudden demise of someone close. On the other hand, in the last short period of demise risk coverage, or additional risks (of non-life nature), life insurance enters a new dimension regarding new circumstances in people's lives, especially in relation to bigger responsibility for family life. This refers to the fact that financial markets offer a number of savings tools (in terms of the savings portion of the life insurance of competitive tools) that can be used to cover elderly needs as well as life insurance.

Today's life insurance in reference to its significance of covering people's needs appears in various forms that combine two basic life events, i.e. demise risk and the rest of one's life, or they include additional risks of non-life nature, such as injuries, illness, invalidity etc., which are closely related to life risks. Relevant forms of life insurance are intended to meet people's needs with regard to their significance. The basic forms of life insurance include:

- term life insurance that includes demise risk coverage, or additional risks,
- endowment insurance that includes coverage of demise risk or additional risks as well as the savings portion (the rest of one's life portion), i.e. the insured person receives arranged insurance money at the agreed time (unless he/she dies in the course of the period of insurance) and the insurance in this form basically represents a certain form of savings production with a yield guarantee (by applying a technical interest rate),
- pension insurance which includes payment of the arranged sum of pension, i.e. repeated amount of money, and possibly other pensions, such as survivor's pension, disability pension,
- children's assurance intended to cover children's needs,
- universal life insurance, a variable and flexible form of a mixed life insurance which allows in the course of the insurance period adjusting parameters of the life insurance to the needs and abilities of the insured person – the method and frequency of the insurance payment, adjustments of the insurance period duration, or the possibility of withdrawing (lending) a part of the savings within the life insurance,
- unit linked life insurance where the insurance benefit depends on the development of prices of shares units of the shares fund in which the insurance premium is invested (Daňhel, 2005, p. 203); the amount of the insurance premium fully depends on the yield from investing insurance reserves and when the insured persons themselves choose the strategy for investing their reserves produced as part of the life insurance.

In terms of proper use of the life insurance to cover the demise risk, or other risks (of a non-life nature), it is significant to set the amount of the insured money. An optimal choice of the insured money for the demise risk is based on several approaches. These approaches are related to the purpose for which the life insurance is arranged as well as to the form of the life insurance. The amount of the insurance money should generally correspond to a certain multiple of the annual net income of the insured person (especially if he provides for other persons in the family and the family income depends on this person's income) and to the amount of outstanding financial obligations (unless they are covered in a different way). The sum insured needs not be constant during the whole insurance period. It may be set as increasing with regard to the development of consumer prices index (inflation), which is naturally connected with the increased insurance premium. Or on the contrary, insurance money decreasing during the insurance period may be concluded. Theoretically, it is possible to define following methods to determine the amount of the sum insured (Ducháčková, 2012, p. 199 – 200):

- determining the sum insured depending on the line of credit,
- determining the sum insured depending on the income level,
- determining the sum insured by being derived from the costs.

Given the perception of the life insurance significance, it is typical for developed countries to apply a certain form of tax allowance of the life insurance. Tax allowance may be applied in a different concept, i.e. not imposing a tax on life insurance yield or by applying deduction of the paid premium from the tax base from the income of the insured persons, or of their employers if they cover the cost of life insurance premium for their employees.

## 4 CURRENT ISSUES OF LIFE INSURANCE

The perception of life insurance only as a savings tool is challenging, for life insurance also includes the risk portion of premium. Competitive savings products often bring clients a higher appreciation, which results from the structure of the insurance price. The price consists of an investment portion of premium, risk portion of premium, administrative expenses and the insurance company profit. The insured persons are rarely familiar with the structure of the insurance price (share of relevant price portions), as well as the progress in the sum of settlement (basically the amount of life insurance reserve).

### 4.1 Appreciation of financial means invested in life insurance

Capital life insurance, where the risk connected with the investment of technical provisions of life insurance is carried by the insurance company, applies the regulation of the investment of technical provisions that are created within this insurance. Following this regulation, insurance companies can invest mainly in more conservative investment instruments (e.g. government bonds). The insurance company ensures the appreciation of the financial means invested in life insurance by applying the technical rate of interest. The level of the technical rate of interest is determined by the insurance company. On the one hand, the technical rate of interest means guaranteed minimum appreciation of the financial means invested in life insurance (investment portion of premium) and on the other hand it affects the price of life insurance – by means of discounting. When determining the technical rate of interest, the insurance company has to take into consideration the situation at financial markets (from the perspective of achievable investment yields), the competitiveness of the life insurance product as well as the regulation of this technical rate of interest (since 2000, the technical rate of interest has been regulated by the state). The state regulates the technical rate of interest by determining its maximum level (see Tab. 1).

Tab. 1 – Regulation of the technical rate of interest in the Czech Republic (upper limit). Source: Regulation effecting some provisions of Act on Insurance No. 303/2004 Coll., Regulation effecting some provisions of Act on Insurance No. 434/2009 Coll., ČNB Official Notification, releasing the maximum level of the technical rate of interest dated 11 February 2010, ČNB Official Notification, releasing the maximum level of the technical rate of interest dated 15 January 2013, ČNB Official information releasing the maximum level of the technical rate of interest dated 19. 2. 2015.

Period	2000-2002	2003–2009	2010-2012	2013-2015	1. 7. 2015 -
Limit TÚM	4.0 %	2.4 %	2.5 %	1.9 %	1.3 %

Freedom of investment applies to unit linked life insurance, where the insurant chooses the method of investing technical provision of life insurance, however, at the same time it carries investment risk. The problem in terms of running the unit linked life insurance lies in the approach towards its sale. It is common that the unit linked life insurance is sold to clients who do not understand the way it works, i.e. they expect outlined yield which is not achieved subsequently. Unlike the capital life insurance, the feature of the unit linked life insurance is that the insurance company does not guarantee the payment of the arranged part at the end of the insurance period; the size of the insurance benefit is based on the value of share units. On the other hand, the products of the unit linked life insurance are more transparent.

Insurance companies do not specify the settlement to their clients in advance (the usual practice is that the amount of the settlement is calculated by means of insurance-mathematical

methods depending on the duration of the period of insurance) although the client could obtain information for the respective years of the insurance period related to the paid insurance premium, capital value of reserves with the guaranteed appreciation and capital value of reserves with the expected value of appreciation, including the method used by the insurance company to determine the level of profit-sharing.

#### **4.2 Intermediated sale of life insurance**

Life insurance is commonly arranged through insurance intermediaries or financial advisors. These sellers are remunerated with commissions for the arranged life insurance. As for the life insurance, these commissions are currently set at high values (savings products of life insurance show around 150-200 % of annual premium). Higher commissions are connected with the sale of the unit linked life insurance. Insurance companies pay such high commissions in order to enhance insurance contracts set of life insurance. On the other hand, this fact often results in efforts of the sellers (of several tens of thousands operating on the Czech insurance market) to sell the life insurance products (especially unit linked life insurance) even to clients these products are not suitable for.

Fig. 1 – Progress of the life insurance reserve (scheme). Source: own processing.

A current problem also related to the sale of life insurance is the so-called „over-insurance“, i.e. sellers of insurance products convince the insurant to cancel the existing life insurance contract giving the reason he does not find it beneficial any more, and to conclude a new contract of an innovated form. This method is certainly profitable for the seller who collects money for the arranged insurance, however, completely disadvantageous for the insured person. Life insurance, especially life insurance with savings portion, has a long-term character and the technical provision of life insurance based on which the insurance company pays the settlement is created only after two or three years after the insurance is arranged, i. e. the client if he cancels the contract prematurely basically pays the cost of arranging the insurance policy and additional cost and the indemnity is not paid to him, or possibly only in a small amount (see Fig. 1).

#### **4.3 Impact of the gender directive on life insurance**

Distribution of life insurance products has been substantially influenced by the so-called gender directive of the European Union (Council Regulation No. 2004/113/ES dated 13

December 2004 effecting the principle of equal opportunities for men and women in terms of providing products and services). Originally, it was to be applied for all contracts starting as at 21 December 2007. The insurance area was granted an exception that allowed departing from this rule if statistical data can confirm diversity in figures related to the occurrence of events for men and women. In March 2011, the European Court of Justice decided that as of 21 December 2012 this exception shall no longer be prolonged. Following this decision the gender cannot be regarded as a factor affecting the probability of demise and the related sum of net premium in life insurance.

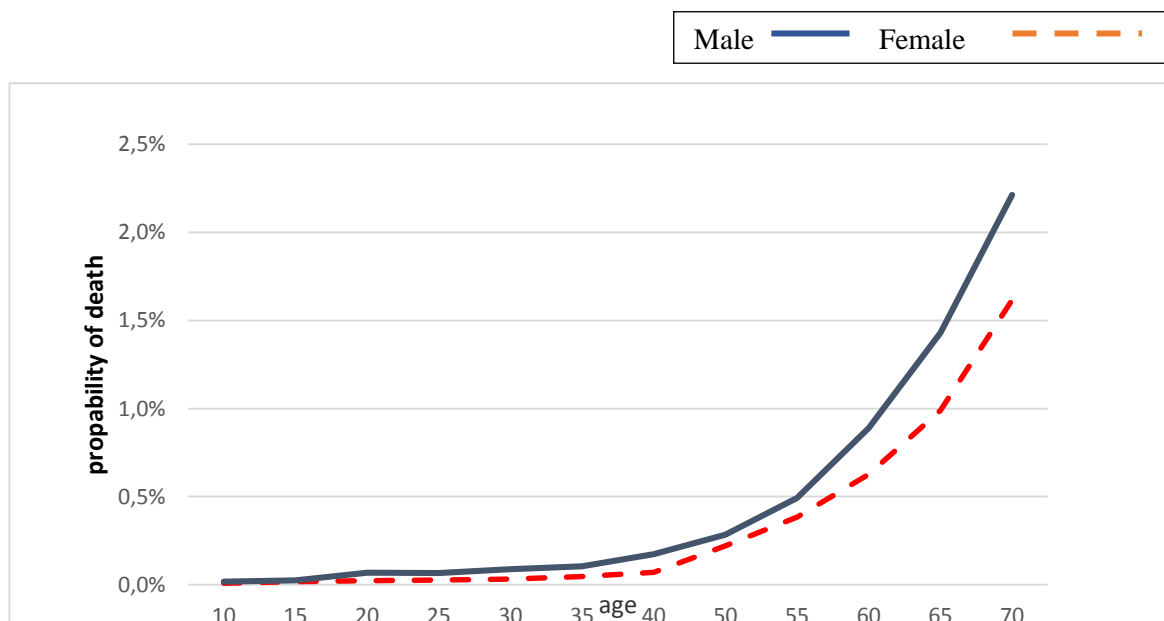

Fig. 2 - Difference in demise probability for men and women Source: <http://www.czso.cz/csu/2014edicniplan.nsf/p/130055-14>.

However, the gender next to age and health represents a significant factor affecting the probability of demise. It refers to an insurance-technical factor and from the perspective of insurance theory the gender consideration as part of determining the price of life insurance cannot be considered discrimination. Another problem might be anti-discrimination efforts claiming that even the price determination based on the age and health is discriminatory (the basics of life insurance would be threatened if these factors were not permitted to be applied in order to assess the demise risk in life insurance). The fact that the gender factor is well-founded is supported by distinct figures about the demise probability of men and women (see Fig. 2) and the medium life expectancy of men and women (based on data <http://www.czso.cz/csu/2014edicniplan.nsf/p/130055-14>):

- Medium man's life expectancy – 74,52 years
- Medium woman's life expectancy – 80,64 years

#### **4.4 Tax advantage of life insurance**

It is a common thing that life insurance is subsidized by the state. The reason lies in the investment nature of life insurance and utilization of life insurance reserves from the macro-economic perspective and recently often in terms of including life insurance in the comprehensive pension scheme. This is the reason why the investment life insurance is subsidized by the state. Life insurance in the Czech Republic has been tax-advantaged since

2001. Tax advantage of life insurance applies to life insurance containing a savings portion, i.e. insurance for the rest of one's life, demise and the rest of one's life, pension scheme. There is a yearly limit of up to CZK 12.000 for the insured persons (if the insured person pays the insurance premium in a lump sum, this whole premium will be proportionally calculated for the whole insurance period due to tax purposes). The employer may include in tax-eligible costs the insurance premium for his employee for life insurance of up to CZK 30.000 per year (alternatively with additional pension scheme) for one employee and this insurance premium is not subject to the income tax of the employer. For this paid insurance premium, neither the employee nor the employer pays the premium for social and health insurance. In terms of the life insurance application, there is great significance in supporting life insurance as well as in the state approach towards the protection of the clients of life insurance companies, especially in terms of the protection of the funds deposited in life insurance. This is the reason for the common investment regulation of technical provisions of life insurance and monitoring the solvency of life insurance companies.

Basic conditions to utilize this subsidy next to the investment character of the insurance are as follows:

- insurance period for the minimum of five years,
- payment of indemnity only after reaching the age of 60 years,
- the insurant is simultaneously the insured person.

Since 2015 another condition to utilize tax advantage has to be met, i.e. life insurance must not allow the possibility of premature withdrawal from the reserve funds. Certain cases showed incorrect utilization of this subsidy, especially when contributions to life insurance were paid by the employers. Employers contributed to life insurance for their employees and the insured person withdrew the insurance amount shortly after having received it. Since the subsidy is intended to create savings for the pension, the possibility of premature withdrawal contradicts this principle. This measure is technically correct given the reasons of tax advantage. To a certain extent (based on existing knowledge), changes connected with the application of another condition to utilize the tax advantage of life insurance shall result in decreased size of the life insurance contracts set.

In terms of the utilization of tax advantage, the sum of the deduction from the income tax base shall correspond to the sum corresponding to the sum which is intended for the savings plan in the relevant year (see Tab. 2). Until then, tax deductions had not been surveyed so strictly.

Tab. 2 - Example case (in CZK) Source: Podávka, 2014 p. 24.

Year	Paid insurance premium	Non-tax risk portion of premium	Reserve related to investment portion of premium (towards the end of the year)	Sum of tax deduction	Payment from reserve
1	10,000	3,000	7,000	7,000	-
2	10,000	5,000	12,000	5,000	-
3	10,000	8,000	14,000	2,000	-
4	10,000	11,000	13,000	0	1,000
5	10,000	13,000	11,000	0	3,000

#### **4.5 Products of lump-sum paid life insurance**

The period after 2000 shows the trend to apply lump-sum paid life insurance products on the life insurance market. They usually represent products with prevailing investment portion and minimal risk portion arranged for four to five years. These characteristics make it clear that it

is actually no longer an insurance product but a savings product. These products basically represent an alternative to some bank products, especially in connection with changes in the area of bank products (e.g. related to the financial crisis) and they are largely offered by bank-insurance institutions. Products of lump-sum paid life insurance substantially influence the indicators of life insurance market (see Fig. 3) although by their nature they are not real insurance products.

Fig. 3 - Development of the prescribed premium of life insurance in the Czech Republic in billion CZK. Source: <http://www.cap.cz/statisticke-udaje/vyvoj-pojistneho-trhu>.

#### **4.6 Unit linked life insurance**

Another area to deal with is represented by the products of unit linked life insurance. In the past, the unit linked life insurance was considered to be suitable for insurants who already are sufficiently provided with the standard life insurance (Hagelschuer, 1991, p. 44; Ducháčková, Daňhel, 2006, p. 382). Generally speaking, this is suitable for clients with certain knowledge and experience of investments. The significance of the unit linked life insurance was growing fast in the 90's of 20<sup>th</sup> century (Nyfeler, Lehmann, 1995, p. 6). The significance and share of the unit linked life insurance on the Czech insurance market substantially increased after 2000 (see Tab. 3). Increase in the share of the unit linked life insurance in the global prescribed premium has been determined by a number of factors, but mostly by the profitability for the insurants (shift of the investment risk to the insurant), thus resulting approach toward the sale through intermediaries (higher commission compared to other insurance products). The unit linked life insurance puts emphasis on flexibility, state subvention and the possibility of higher appreciation.

A big challenge in relation to clients in life insurance is the issue of transparency and comprehensibility of life insurance products. Life insurance products are often intricately formed and incomprehensible to the client. Standard capital life insurance is viewed by the client as a guaranteed product where the insurance company is obliged to pay the previously arranged capital sum. However, misunderstanding the product by the clients may result in taking wrong steps – e.g. premature termination of the insurance policy (especially shortly after arranging the insurance policy) and wrong ideas about the amount of the so-called settlement.

A big challenge in relation to clients in life insurance is the issue of transparency and comprehensibility of life insurance products. Life insurance products are often intricately formed and incomprehensible to the client. Standard capital life insurance is viewed by the

client as a guaranteed product where the insurance company is obliged to pay the previously arranged capital sum. However, misunderstanding the product by the clients may result in taking wrong steps – e.g. premature termination of the insurance policy (especially shortly after arranging the insurance policy) and wrong ideas about the amount of the so-called settlement.

[http://www.cnb.cz/cs/dohled\\_financni\\_trh/souhrnne\\_informace\\_fin\\_trhy/zakladni\\_ukazatele\\_fin\\_trhu/pojistovny/poj\\_ukazatele\\_tab04.html](http://www.cnb.cz/cs/dohled_financni_trh/souhrnne_informace_fin_trhy/zakladni_ukazatele_fin_trhu/pojistovny/poj_ukazatele_tab04.html).

	31.12.2010	31.12.2011	31.12.2012	31.12.2013
Number of contracts	2,024,798	2,618,238	2,867,261	3,029,495
Number of recently concluded contracts	709,748	753,756	729,873	614,011
Prescribed gross premium	33,956,363	36,584,233	37,799,094	34,763,925
lump-sum paid	18,495,718	19,756,620	18,173,544	13,813,301
with recently concluded contracts	19,581,999	19,160,608	18,632,916	12,628,742
Acquisition costs of insurance policies	6,818,930	7,415,447	7,010,366	5,969,490
Cost of commissions for intermediaries	577,270	5,736,525	5,495,480	4,526,489

The unit linked life insurance is connected with the application of a whole range of fees that are intricately formed and often non-transparent. Regular fees of the unit linked life insurance are as follows:

- administrative charges for administrative expenses charged for the whole policy period,
- collection fees covered from each premium payment,
- fees of a certain percentage from the difference between the purchase price and the selling price of share units (bid/offer spread),
- fees to cover initial costs (50 – 70 % of the annual premium of the savings portion for the period of 2-3 years).

Furthermore, the unit linked life insurance is connected with other fees, such as fees for insurance policy cancellation, changes in insurance policies, extra withdrawal of share units.

As a result of the structure of fees, the value of accumulated share units as part of the savings portion of unit linked life insurance at the level of paid premium is achieved only around the tenth year of the policy period (especially due to the fee to cover the initial costs of concluding the insurance policy). It implies that this insurance is suitable only in the long-term perspective.

Considering the long-term nature of unit linked life insurance, an incorrect approach is the termination of the policy after a short time (or concluding a new insurance policy). Also, given the non-transparent structure of the product and the fees, the product is non-transparent.

It is possible to enhance transparency through indicators characterising this product. The client should be provided with more detailed information about the structure of the insurance price (SUN indicator – standardized cost indicator). The price of unit linked life insurance consists of following portions:

- risk portion – intended to cover risks, such as death, injury, invalidity, illness etc.,
- cost portion – intended to cover costs of insurer, such as acquirable commission, collection fee, administrative expenses, claims expenses etc.,
- investment portion – a part of premium intended to purchase share units.

In terms of the product transparency, it is suitable to inform the client about the structure of the insurance premium in the initial phase of the insurance with regard to the basic purpose of the insurance policy and client's expectations (see Fig. 4).

Fig. 4 - Difference in the price structure of unit linked life insurance in % – example. Source: own processing.

To get the picture of the progress of unit linked life insurance, it is advisable to present the insurant with a simulation of the progress of the amount of the life insurance reserve at the start of the insurance. Here, we can see the simulation of the amount of the reserve of a specific life insurance in various variants of the expected appreciation compared with the progress of the paid premium (see Fig. 5).

Fig. 5 - Illustration of the progress of the amount of the reserve of life insurance for individual variants of yield and for a specific case: client's age – 30 years, policy period – 30 years, premium CZK 1,000 per month, capital sum for death – CZK 1 Mio. Source: <http://www.cap.cz/odborna-verejnost/samoregulacni-standardy-cap/modelace-vyvoje-pojisteni>.

In order to enhance the transparency of unit linked life insurance, other indicators may be recommended that provide a better picture, especially about the product expense ratio:

- TANK indicator – expense ratio indicator generally used for investment products with periodical investment – basically an equivalent to RPSN (annual percentage rate of costs). TANK is a ratio of all expected paid fees to expected future investment.
- Ongoing charge indicator related to individual funds of unit linked life insurance and expressing the amount of total costs of unit linked life insurance in relation to average controlled assets within the fund (in short, if a shares fund appraises the means by 5.3 % and the fund expense ratio is 2.1 %, the net appreciation of a share unit is then 3.2 %); the indicator includes all costs connected with the control of the shares fund and generally speaking if the funds are actively controlled, there are higher costs, and the passively controlled funds show lower costs.
- TER indicator (Total Expense Ratio) indicates how much of the investor's property value is represented by the fund administrator costs per year.
- PER indicator (Product Expense Ratio) evaluates the product expense ratio and how much percent of the paid premium will not be invested but used to cover the administrative expenses.
- RiY indicator (Reduction I Yield) that does not take into account the insured part of the product and all fees are expressed with one percent; its flaw is that it can be influenced by the inclusion of some cost portions in the risk portion of premium, which distorts the final evaluation through this indicator.

### **3 FINANTIAL ARBITRATOR**

In terms of client's protection, consumer protection institutions play a significant role. The insured persons may contact these institutions if they face problems related to life insurance products. In some countries, the insured persons may turn to the institute of insurance ombudsman or to the department of consumer protection within the Association of Insurance Companies. In the Czech Republic, the Czech National Bank has the "Consumer Protection Department" to deal with discrepancies during the practice of insurance products (of other financial products). Dissatisfied insured persons may address their inquiries and complaints to the Czech Association of Insurance Companies. Recently, the Office of Financial Arbitrator has started to operate directly in the area of settling life insurance disputes.

#### **3.1 Significance, status and competence of financial arbitrator**

According to the existing legal regulations, the financial arbitrator could be described as a person heading the Office of Financial Arbitrator and deciding disputes that fall under his competence. The status of the financial arbitrator during the decision-making process is given by two basic principles: the proceedings before the financial arbitrator may be initiated by the client of the financial institution, especially a consumer and the financial arbitrator also primarily acts as a board of conciliation. Consumers' dispute settlement, if possible through arbitration, is a trend which is explicitly requested in EU countries and can be considered more acceptable than an explicit decision (finding) (Schlossberger, 2012, p. 304). At present (i.e. January 2015 – authors' note), the financial arbitrator is equipped with following competences for the dispute settlement, which would otherwise fall under the competences of general courts. It refers to following areas (Act No. 229/2002 Coll., on Financial Arbitrator, § 1 par. 1): payment services, issuing electronic money, consumer credits, joint investments through a standard fund or a special fund, exchange office service and life insurance.

These areas gradually became part of the financial arbitrator's competence. Since 2003, where the original act came into force, the financial arbitrator could only deal with disputes resulting

from the transfer of financial means and with disputes arisen between issuers and holders during issuing and using electronic means of payment. The competences of the financial arbitrator were gradually extended and the competences of the financial arbitrator related to dispute settlement of life insurance have been extended since 2013 (Act No. 278/2013 Coll., which among others amended the Act on Financial Arbitrator, with competences extended by dispute settlement between the insurance company or the insurance intermediary and those interested in the insurance policy, insurant, the insured person, authorized person or beneficiary during offering, providing or intermediating the life insurance). The service of the financial arbitrator in this area is available for all insured persons regarded as consumers who are dissatisfied with the life insurance product. This is mainly internal opinion of the insured person that his rights or obligations of the insurance company or another institution resulting from this relationship are restricted or not fulfilled as agreed in the insurance policy. Life insurance products are not simple and may evoke various negative feelings with the insured person. If his complaint submitted at the insurance company, or another institution, is not handled to his satisfaction, he can submit a proposal to initiate proceedings before the financial arbitrator. Unlike the other above-mentioned bodies, the financial arbitrator directly decides that particular dispute as if it were decided by the court.

The proposal to initiate proceedings is free of charge and can be submitted in any form. Among others, the complainant's proposal has to express his requirement, the so-called demand. After the proceedings initiation, he issues within 30 days (or in extended proceedings) a decision in re complainant, i.e. the insured person, which is called a finding. After coming into force, this finding is executable pursuant to the court civil rules. As mentioned before, the financial arbitrator aims to primarily settle the respective dispute through arbitration. If this is not accepted by the one or the other party, he has to make the decision through the finding. Following a legitimate finding, the financial arbitrator has to impose a financial fine, in our case on the life insurance company in question that was unsuccessful in the dispute and the financial arbitrator decided in favour of the complainant, i.e. the policy holder. We may conclude that the finding of the financial arbitrator offers no option to ask the court for its cessation and decision directly by him.

### **3.2 Analysis of disputes**

Analysis of disputes is slightly problematic given the above-mentioned facts that kept changing throughout the period, or rather extended the competences of the financial arbitrator during suits. The following Tab. 4 presents total numbers of suits initiated by the financial arbitrator since his appointment.

Tab. 4 - Numbers of initiated suits. Source: 2013 FA Annual Report.

Year	2003	2004	2005	2006	2007	2008	2009	2010	2011	2012	2013
Number	66	130	160	77	95	99	118	135	167	204	706

Disputes related to life insurance are represented in the table in view of the date of extending competences of the financial arbitrator by life insurance (1 November 2013) to a small extent (see Tab. 5). However, it can be expected that the number and significance of the tackled disputes within the life insurance shall substantially increase considering the nature and a relatively complex structure of individual types of life insurance. Dissatisfaction of some insured persons with the life insurance products, especially the unit linked life insurance, has been manifesting itself for a longer time and it radically increased during the financial crisis. It was demonstrated through a number of complaints and the settlement of these disputes

within the Consumer Protection Department as well as within the complaints submitted at the Czech Association of Insurance Companies. It is a subjective view of the reserves value and the amount of indemnity within the unit linked life insurance often connected with the misconception of the product and insufficient awareness and transparency of the product. With sufficient awareness, this product is unlikely to be sought after. The present figures imply that the extrajudicial resolution of disputes within the life insurance is at the very beginning. Nevertheless, the area of life insurance as part of the new competences of the financial arbitrator is considered to be most sought-after. The significance of the financial arbitrator in terms of the resolution of disputes within the life insurance is going to be enhanced.

Tab. 5 - Areas of disputes from 2011 to 2013. Source: FA Annual Reports from 2011 to 2013.

Area / Year	2011	2012	2013
System of payment	126	72	187
Consumer credits	37	133	502
Joint investments	4	2	0
Exchange offices	X	X	1
Life insurance	X	X	13
Total	167	204	706

## **5 RESULTS**

The structure of the life insurance market change in recent seasons, especially in the sphere of the share increasing is and importance of investment life insurance. This is mainly driven by the way of sale of life insurance products through the agents. Complexity of construction investment life insurance, which has recently become more important, results in problems occurring in the last period. In particular, this is a misunderstanding of the product from the clients 'point of view. It is therefore appropriate to increase the transparency of life insurance. To this situation some indicators may contribute, especially indicator SUN, TANK and other indicators. These indicators will increase the transparency of life insurance products. They can help to the clients to understand the structure of life insurance better; however, they are clear only to certain clients. It follows that investment life insurance is suitable for those clients who are informed about the financial market. On the contrary, for most clients is a more appropriate capital life insurance product. The effort of mainly insurance agents is to sell just the investment life insurance with regard to the possibility of obtaining higher commissions from negotiating insurance contracts. Therefore the institutions for the protection of consumers, which include also the Office of the Financial Arbitrator, play their own role.

Life assurance is regulated by the state. Regulation in relation to life insurance refers to approaches to investing insurance technical reserves, adjustments in tax matters in the life insurance and editing activities of insurance agents. Legislation activities concerning insurance agents belong to discussion in the last few years.

## **6 DISCUSSION**

Indicators which could be an explanation for life insurance products to use, have information capability, explains the base of the product and clients should be familiar with them. The problem is still the complexity of some indicators. Therefore life insurance products will be still complicated for consumers due to their internal structure. For investment life insurance is typical the fact that it is often more an investment product than the product of the insurance

(that is dealing with the meaning of its individual components). It can be discussed whether this product is to be classified as the right insurance products, although in some cases the investment life insurance contains very small insurance component. In some countries these types of products are classed as investment products and regulated as investment products.

Due to the fact that disputes between clients and insurers will exist in connection with the operation of life insurance, it is appropriate to look for the ways how to solve these disputes. These disputes mainly related to the fact that clients often do not understand the base of the product and the fact that the insurance was concluded improperly in some cases. This occurs by the wrong activities of insurance agents. Although new control measures apply towards insurance agents, the basic problem can be very difficult to remove. There is a problem of asymmetric information in relation agent – policyholder and the primary agent's interest - earning commissions (Daňhel, Ducháčková, Radová, 2008, p. 604; Daňhel, Ducháčková, 2013, p. 100). Thanks to this there is also unethical behavior on the market is - so called "over insurance".

## **7 CONCLUSION**

Life insurance products may take various forms which then specify their significance. Recently, life insurance has been wrongly perceived as a savings tool. Life insurance is primarily intended to cover risks. This is the approach that should be adopted. Savings (especially for the old age) is a specific portion of life insurance. There are indicators contributing to better transparency of the product that are used to clarify its form and subsequently the size of indemnity and the possibility of tax deduction. That especially applies to the unit linked life insurance which is primarily intended for clients who are aware of the investment nature and possible consequences for the final size of the indemnity at the end of the insurance policy. In spite of this, new ways of resolving disputes between the insured and the insurance companies are still being searched for. Life insurance is an area of the financial market which does not involve simple products. It provokes various questions that need to be clearly and comprehensibly answered to consumers. However, if a situation arises when the consumer as insurant is not content with the product because he expected a different result, he may file a complaint with the financial arbitrator if he was rejected by the respective contractual subject. The financial arbitrator will then (pursuant to valid legal regulations and the respective insurance policy and insurance clauses) assess the relevant dispute objectively and justly as if it were assessed by the general court. Proceedings before the financial arbitrator are faster, more efficient and free of charge for the consumer as insurant. In order to ensure a more frequent use of his services, it is necessary to raise public awareness of his existence.

## **DEVELOPING SUPPORTING INDUSTRIES THROUGH BUILDING INDUSTRIAL CLUSTERS IN VIETNAM**

*Dung Vu Tri, Huyen Pham Thi*

### **Abstract**

The Vietnamese Government, highly concerned with the development of supporting industries, has created various policies and proposed a number of solutions to promote the sustainable development of supporting industries. "Industrial cluster" is an important policy tool that is widely used worldwide. International practices have illustrated that the development of an effective industrial cluster network will strengthen the competitiveness of enterprises. However, industrial clusters have not resulted in positive impacts on the development of supporting industries as they were expected. Sustainable growth of supporting industries requires a proper policy from the government, and the Master Plan for the Development of Supporting Industries must be designed to meet this requirement. This article refers to the building of industrial cluster as a solution for the development of supporting industries in Vietnam. We hope that Vietnam's industries can play an important role in the economic development, based on the strategic linkage around an anchor firm, so that it form a cluster. It should be the focused issue of the master plan for developing supporting industry.

This paper aims to clarify the importance of supporting industries in Vietnam to meet the mission to become an industrialized country in 2020. Obviously, Vietnam couldn't become an anchor country in industry. It should find out the way to join international value chain for some original industries. So that, building industrial clusters can be considered as the best approach for Vietnam at this direction.

## **1 LITERATURE REVIEW**

### **1.1 Overview of supporting industry**

Many researchers and policy makers use the term "supporting industries," but its origin and original meaning are at times ambiguous. Researchers tend to define the term according to their subjective understanding and purpose. In fact, "supporting industries" is a Japanese English term employed first by Japanese enterprises long before becoming an official term. It gained popularity in Japan in the mid-1980s when the Japanese government used it in its documents, as explained below, and has been widely used in Asia ever since. The idea of supporting industries is now routinely discussed in regional meetings on the development of small and medium enterprises (SMEs).

The term "Supporting Industry" appeared in Japan in the 60s of the last century. The "Supporting Industry" phrase itself is directly translated from the original term in Japanese "San-no San-gyuo", in which San-no means "Piedmont" and San-gyuo is "Industry".

Although the term "supporting industries" is widely used in many countries, it is still ambiguous and without consensus in definition. Whether "supporting industries" is understood broadly to include all industries that provide production inputs or narrowly as

industries that provide only parts, components and tools for certain industries depends much on the user.

On a practical level, the leather footwear industry needs industries which produce parts of footwear, processed leather, leather working machinery, and design services. Supporting industries of the motorbike industry supply motorbike assemblers with material inputs and their processing as well as services. On the other hand, supporting industries also refer to industries that are much broader and without a clear borderline. For policy formulation, the scope of supporting industries must be concretely and strategically specified by policy makers in a way that ensures consistency between definition and policy purpose.

For instance, Thailand defines supporting industries to be enterprises that produce parts and components used in the final assembly processes of the automobile, machinery and electronic manufacturing industries (Ratana, 1999). Meanwhile, the US Department of Energy defines supporting industries as those that supply materials and processes necessary to form and fabricate products before they are marketed to end-use industries (2005: 1). In Vietnam's current context, it is hardly practical to import any existing concepts of supporting industries because of differences in economic conditions, development level and the degree of challenges that each country faces in the global economy. It is necessary for Vietnam to single out a definition of supporting industries that is the most appropriate for its own socio-economic conditions.

The term "supporting industries" currently used in East Asia originated from Japan in the mid-1980s. The first official document to use this term, as far as we can identify, was the White Paper on Economic Cooperation 1985 by the Ministry of International Trade and Industry (MITI)<sup>1</sup> of Japan, where the term "supporting industries" was used to refer to "small and medium enterprises (SMEs) that contribute to strengthening industrial infrastructure in Asian countries for medium and long terms" (1985) or "the SMEs that produce parts and components". The purpose of MITI at that time was to promote the industrialization process and the development of SMEs in ASEAN countries, especially in ASEAN 4 (Indonesia, Malaysia, Philippines, and Thailand).

Comparing the entire process of producing a product with a mountain, the supporting industries is like the piedmont, while assembling industry and finished production play the role of mountain peaks. Therefore, without stable support industries, there would not be a sustainable and effective assembling and finished production industries. With this vision, the overall industry can be seen as the combination between supporting industry and final assembly industry. In this, supporting industries are usually referred to as industries that manufacture high-quality production parts, tooling, and machinery that directly "support" the final and sub-assembly processes.

Regarding business organization, supporting industries consist of three types of firms: i) parts and machine tool suppliers located in foreign countries (called "import" afterward), ii) the foreign parts and machine tool supplier located in the domestic market (called "foreign supplier" afterward), and iii) domestically-owned parts and machine tool suppliers (called "domestic supplier" afterward), which are usually small and medium size enterprises (SMEs). In addition, customers of supporting industries are domestic assemblers, foreign assemblers located in the domestic market, and foreign assemblers located in foreign countries. Foreign assemblers are often multi-national corporations (MNCs or called "MNC assembler" afterward).

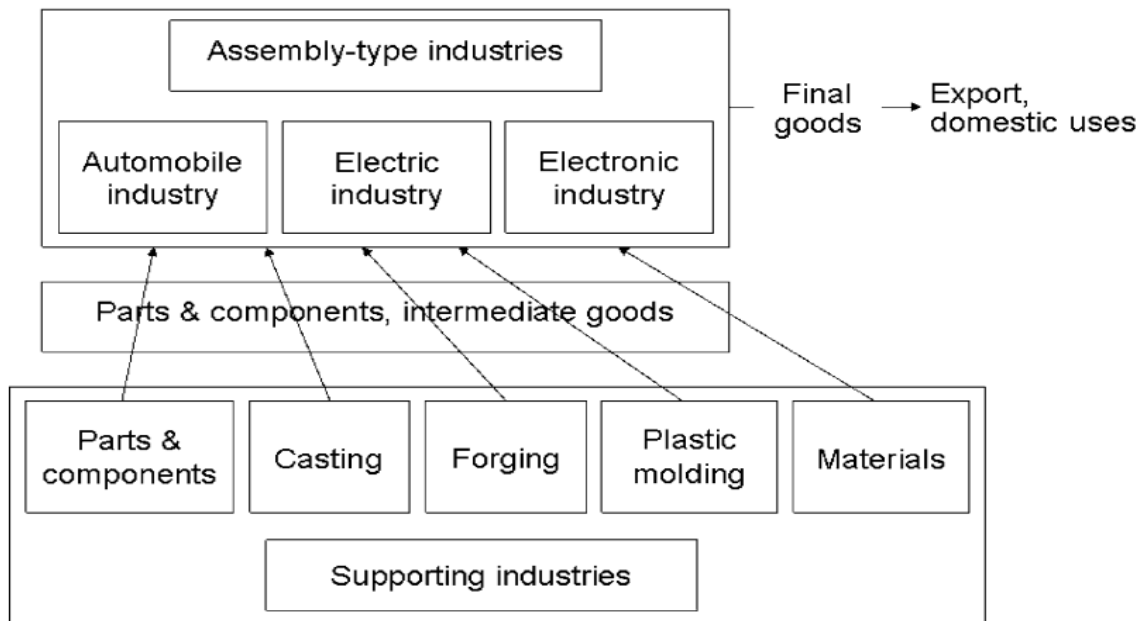

Fig. 1 – Scope of supporting industries according to MITI. Source: Kenichi Ohno (2007)

The decision No. 12/2011/QĐ-TTg of February 24, 2011 on development policy of a number of supporting industries states that: “*Supporting industry* means an industry that manufactures materials, spare parts, details, accessories and semi-finished products supplying to industries that manufacture and assemble finished products for use as production materials or consumer goods”.

Eventually, supporting industry is considered as the piedmont, providing the hard base for the mountain and the peak which include production, industrial assembly and consumption. And supporting industry can develop in parallel or pioneer to form the development basis for key industries such as automobiles, motorcycles, electronics, textiles, footwear, and telecommunications.

Vietnam adopted the term “supporting industries” relatively late. In the past, concentration on the development of heavy industries in the centrally-planned economy required a wide range of production inputs. Vietnam underestimates the importance of supporting industries because parts and components for finished products of such industries such as agricultural machines, bicycles, and automobiles were produced in-house and in a vertically integrated fashion. Even when the term “supporting industries” was introduced in most Asian countries at the meetings of the Asian Productivities Organization (APO) and the Asia-Pacific Economic Cooperation (APEC), Vietnam, which was in the early years of the Doi moi process, continued to pay little attention because it was dealing with other urgent issues such as agricultural revitalization, hyperinflation, economic reform, and poverty alleviation.

When foreign investors first entered the Vietnamese market in the mid-1990s, it was difficult for them to find qualified local suppliers for production inputs. Foreign firms had soon singled out this problem and urged the Vietnamese government to seek solutions. However, at the time the Vietnamese government was not familiar with the concept of supporting industries. The problem rooted in the absence of a legal definition for supporting industries that prevented any effective execution of proposed measures.

## 1.2 Overview of industrial cluster

The United Nations Industrial Development Organization (UNIDO) defines industrial clusters as followed: “Industrial cluster is a geographical concentration of firms, especially SMEs, in the same sector. They include, for example, suppliers of specialized inputs such as components, machinery, and services, and providers of specialized infrastructure; therefore, they have the similar advantages and disadvantages”. This definition by UNIDO emphasizes the geographical concentration of firms with internal linkages, whereby cluster gains are furthered by local firm cooperation, local institutions and local social capital. The growing evidence on small firm clusters in developing countries competing in local and global markets has driven much of the policy enthusiasm in promoting clusters.

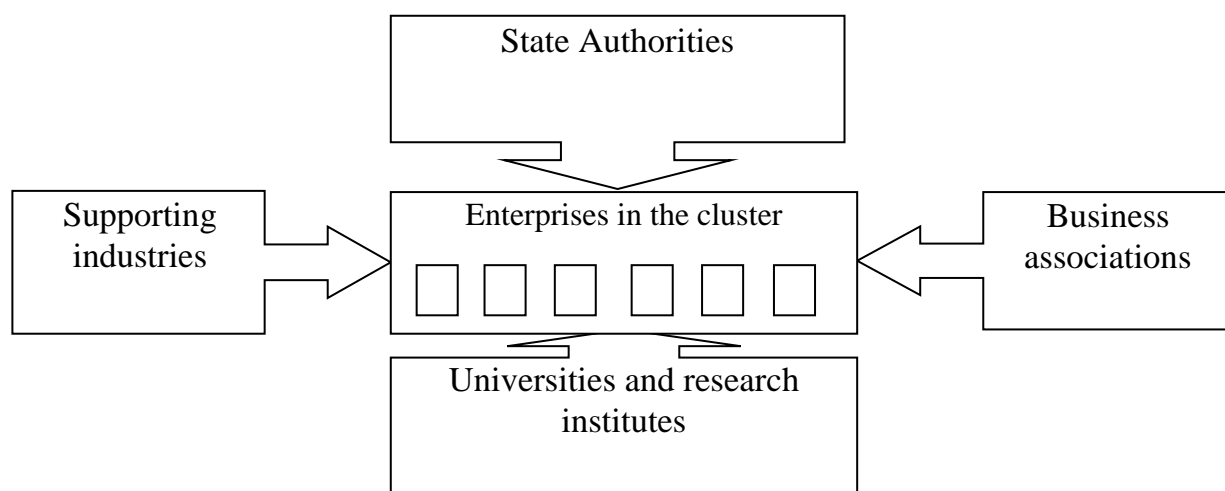

Fig. 2 – A typical industrial cluster. Source: Tran Kim Hao (2011)

Michael Porter (Harvard Business University) defined industrial clusters with 3 key elements: (1) the geographic concentration of interconnected companies and institutions in a particular field; (2) An array of linked industries and other entities; (3) Cooperation and competition among the players in the industrial cluster.

According to definition, concept and diagram of industrial cluster, there does exist a close relationship between the development of industrial clusters and supporting industry. On one hand, the development of industrial cluster is the conditional to the development of supporting industry. In fact, the growth of a cluster usually brings chances to supporting industries. SMEs in supporting industries can access to huge markets and gain support from big corporation to have modern technology.

## 1.3 Industrial cluster and supporting industry

Industrial cluster is formed by the gathering of firms in some closely related industries and sectors, therefore the role of supporting industry can not be denied. The growth of industrial cluster also led to the development of core industries. Industrial clusters featured by high product volume due to concentrated production, high and stable quality, jobs creation, FDI attraction..., will facilitate the domestic firms to develop their capacities to serve. Supporting industries will be strengthening.

On the other hand, the development of supporting industry will facilitate the effective performance of the industrial clusters and enhance the competitiveness of enterprises in the clusters because the development of industrial clusters also significantly depends on the development of supporting industry. According to Mr. Patrik Gilabert, Vietnam is not only operating industrial zones, industrial area, but also industrial clusters. Industrial clusters help to realize the core competitiveness benefit thanks to the concentrated scale, population and urban development.

In industrial clusters, the linkages between firms are reflected in many perspectives, but the most important is economic perspective. In other words, the players in industrial clusters provide products and services to each other. Outputs of one firm can be an input of others or they join together in producing a commodity or operating in one field ... Here, the linkage is positive and effective. They would work together to share information, jointly order products and trainings. The cost of shipping and environmental treatment can be effectively minimized.

## 2 RESULTS AND DISCUSSION

### 2.1 Current development of supporting industry

Currently, Vietnam’s industry mainly relies on processing and assembly production such as textiles and footwear processing, footwear, assembly of automobiles, motorcycles, electric and electronic devices ... resulting in low added value and weak competitiveness of enterprises. The culprit in this situation is the poor development of supporting industry in Vietnam.

Fig. 3 – Import of computers, mechanic products and accessories. Source: Vietnam’s Custom Department, 2012

### **Supporting Industry for electronics, information technology**

Domestic investment in electronics and information technology is limited with the majority comes from FDI enterprises. More important, the product portfolio there also seriously imbalanced, mainly civil products. It is lacking of specialized electronic products (accounting for only 10-12% of products from the industry), and most of them are using out of date technology, low competitiveness with most of raw materials are depended on foreign suppliers.

Particularly, none of Vietnam's industrial manufacturer participates in the production of electronic materials. The mechanical engineering, electronics, information technology ...imports almost all of raw materials from Japan, South Korea at a very high price. This lacking of stable and affordable sources for raw materials result in difficulties for enterprises when competing with foreign firms.

### **Automotive Supporting Industry**

Automotive assembly production is met with high expectation due to preferable development policy, but the localization rate is still very low, approximately 10% for cars because the low market volume can not attract spare part producers to participate in the supply chain.

At the moment, the automobile manufacturing industry of Vietnam is considered to be rather weak compared to other regional countries, while Mazda, then Ford has recently abandoned the car production project from 700 million to 1 billion USD in Vietnam because they can not find the supply for simple components like screws, wires or plastic. Vietnam's automobile industry will face fierce challenges when Vietnam starts to implement the AFTA commitments on tariff reduction in 2018.

### **Motorcycle Supporting Industry**

In Vietnam, motorcycles account for 90% of traffic vehicles. In the beginning, 100% of the products are imported from abroad. At the moment, supporting industries in Vietnam can produce about 70% of the components and parts, contributing to high localization rate of motorcycles manufactured in Vietnam. However, the cost of parts, accessories from domestic production is still high and of unstable quality.

The current development of Vietnam's supporting industry can be described through the opinions of Mr. Keisuke Kobayashi, Project Director from office of The Japan External Trade Organization (JETRO) in Hanoi. "Many Japanese enterprises with investment in Vietnam have difficulty in purchasing parts here. The shortage of Vietnamese enterprises with relevant capacity required by the Japanese enterprises and the lack of information on the supporting industries are major barriers in the cooperation between enterprises from the two countries. According to Dr. Le Dang Doanh, former Research Director of the Institute for Central Economic Management, restrictions in the chain or cluster linkage in Vietnam are major barriers that make it difficult for Vietnamese enterprises to obtain a raw material supply contract for big enterprises.

## **2.2 Current development of industrial clusters**

Some sectors of Vietnam's economy has implemented industrial linkages and participated in the global value chain, but mainly due to the market imperative. For example, the textile industry and leather processing, 20-30 % of raw materials are processed is within the country, while 70-80% of those are counted for overseas processing due to imported raw materials. Similarly, the localization rate of the automobile industry remains low, currently only about

5-10%. More than 90% of automobile parts and components are imported from parent companies or foreign suppliers. In mechanics, there is a significant imbalance between assembly industries and spare parts and materials manufacture. For a number of enterprises producing spare parts and accessories, there are only 20-40% of materials are localized and focused on packaging, plastic parts, and mechanics. The remaining portions are imported from oversea.

Vietnam's economy has integrated into the world at a deeper level. However, its growth pattern and industrialization process reveal weaknesses such as: cheap labor based width growth, capital intensive, low labor productivity, mainly processing and assembly with low added value. Therefore, Vietnam needs to improve its competitiveness, build up industrial strategy, and focus on industrial cluster performance to achieve development goals.

In Vietnam's context, the "industrial cluster" model is unclear with loose linkage between internal and external firms and low industrial content of the exported products. At the beginning, mechanics supporting industrial clusters are spontaneously formed and developed with low sustainability and dynamism, loose linkages, limited connection among internal and external enterprises in clusters. Therefore, Vietnam does not have effective strategies and policies on formation and development of industrial clusters in order to enhance the sustainable competitiveness of the economy. Moreover, supporting industries, among other key players in industrial clusters, are also currently underdeveloped with weak production network and low value chain.

Over the past few years, Vietnam lacks practical policies on effective development of industrial clusters. Activities related to industrial linkage and concentration, production segmentation, value chain and production network... are neglected by the government, business associations and industries. In the industrial development planning, location issues are often the primary concern while the development of industrial clusters in the area receives limited attention. Therefore, in the future, each industrial cluster must include leading firms. Supply chain and business background with the basic economic and production factors (human resources, technology, capital access, business environment, and infrastructure) should be particularly emphasized.

### **3 CONCLUSION AND RECOMMENDATION**

An important goal of building industrial clusters and attaching them with the development of the supporting industry is to create sustainable linkages among players and to enhance the competitiveness of enterprises. In order to contribute to the supporting industry development, building of industrial cluster needs to respect following basic notions [8]. First, developers must ensure that industrial clusters complement each other; the goal is to increase the competitiveness of the enterprises in the clusters. Second, industrial cluster development can be achieved by various methods, depending on the product value chain. One possibility could be a dominant nuclear business with several surrounding the satellite industries; or a string of businesses in the same sector, each take part in a certain production or assume the role of transit for a finished product.

The question is how to develop supporting industry through industrial cluster? What if industrial cluster formation does not result in expected development of supporting industry? In the project "Industrial Zone and Cluster Development, in association with the supporting industry development, production linkages and value chain formation" by the Central Institute for Economic Management (2011), the authors asserted: "the development of industrial clusters in association with supporting industries will promote the formation of production

linkage chain and save time for partnership searching, reduce costs, quickly launch more designs, new items and diversified portfolio of products "[3].

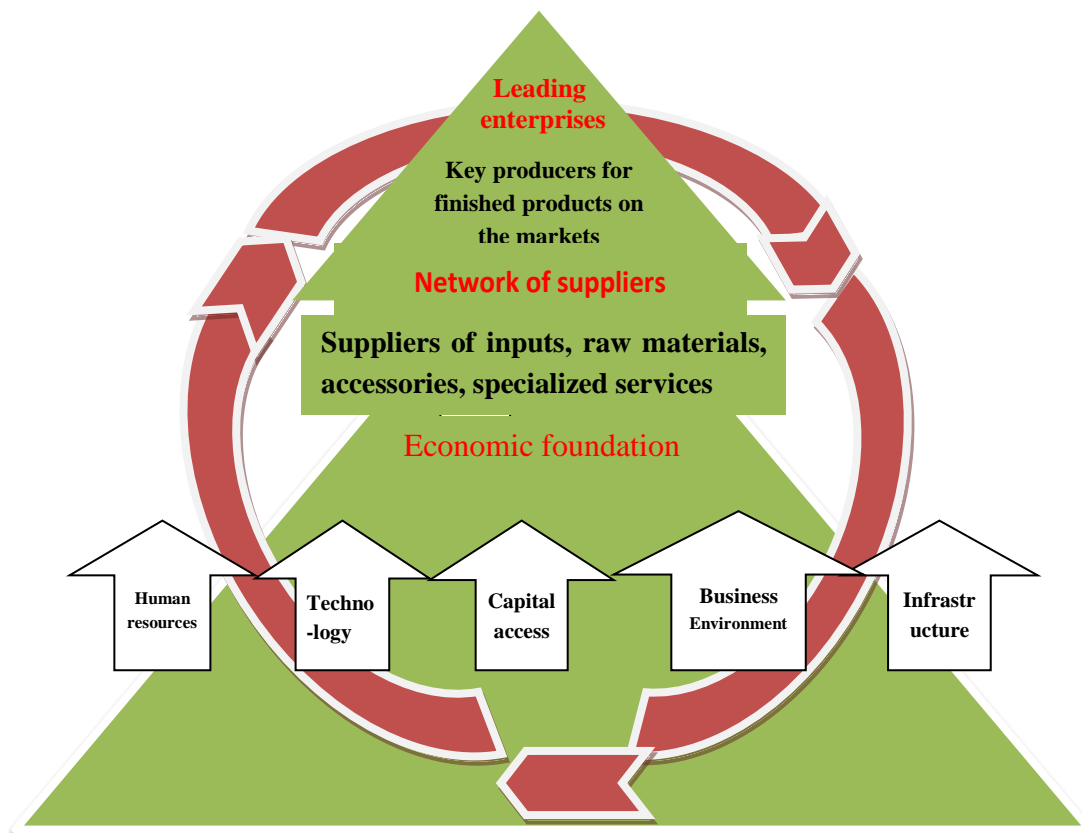

Fig. 4 – Mountain model for Industrial Development. Source: Vietnam's Mechatronic Development Action Plan, 2011

In principle, the Vietnamese Government encourages and creates favorable conditions for the formation of manufacturing focus, manufacturing and industrial clusters, and supporting industries, where production firms in the above mentioned areas can supply products to each other in the production network.

Obviously, the basic conditions for the effective development of any cluster are the economic foundation with fundamentals such as human resources, technology, capital access, business environment and basic infrastructure. On this foundation, the linkages, partnership, competition, supply, consumption and production of gathering enterprises will be naturally and effectively formulated and developed, offering a network of suppliers of production inputs (goods and services) for flagship manufacturers including domestic and international groups or multinational corporations, who then will produce the finished products for final consumption. By that, the competitiveness of the industry cluster is improved so as they are eventually capable of participating in the higher segments of global value chains.

The reality in Vietnam has indicated that business environment factors have strong impacts on the development of industrial cluster and supporting industry. Therefore, it's necessary to build up industrial clusters according to business environmental factors. Theoretical and practical evidences proved that locations with stable and attractive business environment are more lucrative to businesses and investors (especially foreign investors).

Since 2005, the Vietnam Chamber of Commerce and Industry has collaborated with the project Vietnam Competitiveness Initiative (funded by the U.S. Agency for International Development - USAID) to perform studies on Provincial Competitiveness Index (PCI), represented the voice of the private sector to support national and provincial reforms based on specific, measurable indicators of underperformance. The PCI provides a transparent, evidence-based ranking and analysis of the regulatory environment and economic governance in all 63 provinces. [10]. Apparently, for the majority of enterprises (mainly SMEs) in supporting industry, development policy for the private sector will certainly create a favorable environment for businesses in supporting industries.

With this approach, the province with high PCI will likely attract businesses and investors. This is the basis for the formation of the industrial clusters, where the sectors with local investment priorities are regarded as the key industry. The ability of local enterprises to work together is the success factor for industrial cluster development.

Competition among locations promotes business dynamics of players in local industrial clusters and creates pressure for subsequent improvement and innovations. Strong local competition forces businesses to develop new products, improve existing ones, reduce costs and prices, developing new technologies and improving quality and service. Competition also encourages cooperation and mutual support among enterprises in the local industrial clusters. The cooperation among enterprises enhances the possibility of talent attraction, advanced technology application, prestige to corporate image, industrial clusters and their position in the market.

Industrial cluster development allows businesses in supporting industries to implement vertical integration and vertical linkage strategy. This may also improve the business situation of highly specialized enterprises. For instance, this could be a good solution to increase profits, as each production stage will bring about the profit. The final purpose is to obtain surplus value at each production stage as well as in service stage after the final production. In reality, firms in supporting industries often adopt the downstream vertical integration strategy without taking the leading role which should be of the manufacturers of the final products. This strategy allows SMEs to enhance the technical advantages and improve their competitive position on the market.

For a successful linkage strategy, firms in supporting industries should understand the important standards under which the enterprises in final production industries select the input suppliers or satellite businesses. Typically, the partnership or outsourcing decisions by enterprises in final production industry are based on the performance, efficiency and uncertainty level in different situations.

Industrial cluster Development also allows firms in supporting industries to implement horizontally strategic alliance and cooperation. Recently, enterprises in industrial clusters keep developing business relationships and joint venture cooperation with each other in order to reduce costs and jointly make use of resources (labor, relations...). This strategy allows supporting firms in industrial clusters to achieve “economies of scale and experience”, at the same time, increase the market coverage (in terms of both geographical and customer segments). This strategy also facilitates enterprises in minimizing risks of penetrating new markets (particularly financial risk) or expanding business. Cooperation does not only encourage the creation of new products / services, but also reduce the production cost (scale advantage, cost savings on inputs...) as well as minimize or avoid operation risks. Finally, a joint venture between supporting firms in industrial cluster will establish an optimal power block to create competitive advantages.

## **HOW STRONG POSITION HOLD THE IFRS IN THE WORLDWIDE FINANCIAL REPORTING?**

*Martin Dvořák, Libor Vašek*

### **Abstract**

International Financial Reporting Standards were established as International Accounting Standards in 1973 to be generally worldwide accepted language for financial reporting. Nowadays it is more than 40 years since the beginning of the international accounting standards and there is no doubt that IFRS become the lingua franca for financial reporting of companies whose securities are traded on public markets. IFRS is very close to accounting profession and has been included in accounting education of University programs and various chartered accountants programs. IFRS has become an ordinary part of our professional life. Despite all these facts the goal of the paper is to provide an analysis of three aspects such as number of countries have already adopted IFRS, number of companies presenting figures based on IFRS and market capitalization of those companies and to express opinion whether IFRS can be really designated as global standards for financial reporting. The analysis is based on findings resulting from the IASB's survey which was finished by 138 countries till November 2014.

*Keywords: IFRS, financial reporting, adoption, jurisdictions, globalization*

JEL Classification: M48

## **1 INTRODUCTION**

International Financial Reporting Standards (IFRS) were established as International Accounting Standards in 1973 to be generally and all over the world accepted language for financial reporting which is adopted on voluntary basis (Camfferman&Zeff, 2007; Zeff, 2012). Approximately 30 years later, there were first decisions regarding mandatory adoption such as the decision of the European Union. Other countries such as Australia, Hong Kong, South Africa followed. Nowadays it is more than 40 years since the beginning of the international accounting standards and there is no doubt that IFRS become the lingua franca for financial reporting of companies whose securities are traded on public markets. IFRS is very close to accounting profession, especially in Europe. IFRS has been included in accounting education regardless we talk about University students or chartered accountants. IFRS has become an ordinary part of the life for lots of people. Despite all these facts can be IFRS really designated as global or worldwide standards when criteria such as number of countries using IFRS or number of companies already adopted IFRS are used? We hypothesize that a perception of IFRS is highly influenced by countries in which we operate and companies that are considered and not in all aspects IFRS are global standards.

## **2 REVIEW OF LITERATURE**

The last decade has seen significant progress in adoption of IFRS across the countries or international political and economic groups of states. Ian Mackintosh, Vice-Chairman of the IASB, said in November 2014 that last 10 years were sometimes difficult but absolutely successful for IFRS (Mackintosh, 2014). Many papers on the analysis of international implementation of IFRS are built largely on an abstract concept (Ball, 2006) or are focused on

certain country such as the Czech Republic (Prochazka&Ilinitchi, 2010; Istvanfyova, Mejzlik&Pelak, 2010). Other paper examined if and what kind of economic consequences have raised due to an adoption of IFRS which can be mandatory or voluntary (Daske, Hail, Leuz& Verdi; 2008).

In December 2013, the International Accounting Standards Board as responsible body and standard-setter published a statement about International Financial Reporting Standards (IFRS) to be a global language in financial reporting(IFRS Foundation, 2013a; Pacter, 2014) which makes the financial information more comparable, particularly in spatial scale. The statement was based on a global survey focusing on local implementation of IFRS into national jurisdiction of each country. The global survey was finished by 138 countries around the world till November 2014 (IFRS Foundation, 2014). The survey and its findings have been used as a basis of this paper which tries to bring not widely used synthetic view of the current global position of IFRS. The analysis is based on 3 quantitative aspects which are (i) number of countries using IFRS, (ii) number of companies presenting figures based on IFRS and (iii) market capitalization of those companies (as more relevant aspect than the absolute number of companies above). The main goal of the paper is to analyze all quantitative aspects to express an opinion whether IFRS can be really consider as the global standards of financial reporting. The wide scale of publicly presented statistic data compared with the IASB survey data has been used for the purpose of our analysis (IFRS Foundation, 2014).

### **3 IFRS FROM THE PERSPECTIVE OF QUANTITATIVE CHARACTERISTICS**

The following analysis uses data primarily from the ambitious project of the IASB that collects information about national processes of IFRS implementation through a global survey, on the contrary, tries to grasp quantitatively the status of IFRS in the world from three perspectives mentioned in the previous part.

#### **3.1 The number of countries and enforcement forms of using IFRS**

With the new millennium, when the standards were approved by IOSCO (Garbutt, 2010), IFRS have begun to strengthen their position.

Fig.1 - Number of states allowing or requesting the IFRS application. Source: Self; based on relevant IFRS Foundation annual reports 2004 – 2013

The Figure actually characterizes the situation where every individual country permits using IFRS at least. Several specific approaches have been identified through the global IASB survey:

- (i) required by law (for the particular entities),
- (ii) permitted by law,
- (iii) required/recommended by appropriate professionally-accounting authority (e.g. Accounting Standards Board),
- (iv) required/recommended by special authority for certain sectors (e.g. Banking Supervision Commission),
- (v) other (use IFRS without prior legislative or professional requirement, e.g. due to previous use of US GAAP or other historical experience).

The legislative support (the first form of five alternatives above) has the strongest representation amongst the ways of implementation. The EU member states can be included here due to following the effective European regulation (Berger, 2010). In contrast, the strong position of professional and accounting authorities can be found in addition to traditional developed countries (like the US or Japan) for instance among African countries (Kenya or Zambia). The last form of IFRS application (permission or requirement to use the IFRS on the basis of historical experience) is typical for Caribbean states.

Fig.2 - Number of countries with IFRS implementation by the law or other forms. Source: IASB survey of jurisdiction profiles made in 2012

Three-quarters of countries implemented IFRS by the legislative way. From a legal perspective, it can be said that the law is a strong legislative instrument because the possible annulment process is relatively rigid. On the other hand, it is not so probable that abolition of requirement (permission respectively) to report in accordance with IFRS sometimes happens. One of the main reasons why this cannot be practicable is that legitimate adoption of IFRS in principle was based on initiative of the external environment, not on the whim of the legislature. This statement is supported by Judge, Li and Pinsker (2010). They stated that the implementation of IFRS is not assessed under the economic terms, but from an institutional perspective. Therefore, such adoption is relatively enforced because the main motive of approval is “not to fall out of line” or “not to be considered as reactionaries”.

The remaining quarter includes the states delegating the power to prescribe the accounting framework to professional organizations or the states that do not specify any mandatory framework for financial reporting, and thus the entities (listed) can choose from a wider range the suitable one according to their preferences (e.g. IFRS). Most of African or Caribbean countries fulfill this condition as mentioned previously.

This subsection should be analyzed from another point of view as well - the time evolution of the initial implementation (by any kind of forms, e.g. approval/amendment of accounting legislation or accepted doctrine of responsible professional institutions). It is possible to construct the following Fig.3 from the input data (responses from 122 of 138 countries in total) of conducted global survey. At this moment it should be noted that the Figure does not include all the states which hypothetically may use the IFRS. The diagram incorporates only the countries that have released a particular year, when the initial official declaration leading at least to permission of IFRS was made. Thus, there is a possibility that some countries had applied IFRS before this stated official date. Nevertheless the following chart contains relatively accurate figures bringing solid, comprehensive and essentially undistorted view of the IFRS expansion in the world. The importance of the Fig. is growing with the fact that no official source with exact data about the IFRS expansion from time perspective can be traced.

The Figure 3 shows that a significant IFRS expansion occurred in several waves. It can be seen three significant moments for the entire history of IFRS – years 2001, 2005 and 2012 (see Tab. 1 in detail). The time period until 2001 was linked to a moderate trend of adoption with a few incoming countries per year. Still in the early 80s it was not possible to talk about the IFRS (IAS respectively) as a comprehensive set of standards. And thus, the absence of many important standards could not increase the attractiveness logically. It should be noted that their position was not better even in the nineties. Some external stimulus introducing the IAS in a better light or bringing the serious respect was lacked. Such moment occurred in 2000 when IOSCO decision on suitability of use IAS (by listed companies) was made. The application of IAS spread in eleven other countries thanks to this important signal.

Tab. 1 - IFRS expansion in representative years in continent structure. Source: Self; based on IASB survey of jurisdiction profiles made in 2012

Number of countries in continent structure	2001	2005	2012	Total
Africa	2	3	1	6
Asia	1	2	4	7
Australia and Oceania	-	1	-	1
EU	-	25	-	25
Europe (the rest)	-	4	3	7
South America	-	-	1	1
North America	8	-	3	11
Total	11	35	12	58

On the other hand it is true that high absolute number of countries that adopted the IAS in 2001 does not mean a significant global impact in this case. Indeed, eight of eleven of these countries were island states in the Caribbean (see Tab 1).

With respect to absolute number of countries and their economic power, the most important year was 2005. It was strongly influenced by the mass transition of all EU member states

under IFRS. Namely from 1st January 2005 at least the consolidated financial statements of companies listed on EU regulated markets had to be prepared in accordance with IFRS.

Tab. 2 - EU transition under IFRS measured by economic power (GDP, current price, 2004).  
Source: Self; based on IMF data.

Region	GDP (bn. USD)	EU proportion in global economy
European Union	12 694,61	31,21%
World	40 670,54	X

Fig.3 - Number of countries and official IFRS implementation (both realized and planned) - time evolution. Source: IASB survey of jurisdiction profiles made in 2012.

This moment can be considered as unprecedented and clearly the most significant advancement ever the IFRS Foundation and the IASB reached. The representatives of the IFRS Foundation themselves are aware of this fact, as well as the fact that this will not happen again. Nevertheless they have begun to hope that many other countries will follow this expansion process. The Figure 3 shows that it was a relatively realistic estimate. The number of countries using the IFRS has increased by 39 between 2006 and 2013. Although their number was growing slowly but it is a third of the entire set of 116 countries which represents a respectable number for 8 year period if it is taken into account that the first third was achieved essentially until 2003 (22 years since 1981).

The last major anomaly in the observed trend was 2012. In this year 12 other countries implemented IFRS and some of them can be considered as global players such as Russia, Mexico, Argentina and Saudi Arabia. For example, Saudi Arabia however does not require IFRS for all listed companies but only for entities engaged in banking and insurance. Probably one of the compelling reasons why the strong economy (and with them others) resorted to

IFRS implementation, rested in the recent economic crisis. The countries were trying to strengthen a confidence in capital markets by this step and thus encourage activity on them.

Currently about 116 countries through the official implementation use IFRS to some extent (see Figure 3). If the ratio of this number to the total set (expressed by 193 UN member states) is constructed, 60% of all countries in the world have a practical experience with IFRS in their territories. The IFRS Foundation expresses the similar results with fiscal indicators where the mentioned countries represent (in 2012) more than half of world GDP, namely 23,300 bn. USD. The European Economic Area (EU 28 members + 3 associated countries) comprises 17,200 billion USD. Although these figures look auspicious, there is no reason for the undue gladness. A number of world economies and global players have still resisted, although they have acceded to the convergence process. It is talked about China, Japan, India, and last but not least, the most sensitive subject of interest – the United States.

### **3.2 The number of companies and their categories**

IFRS have, in the words of the IFRS Foundation, ambition to be globally accepted accounting standards. The number of countries where IFRS are implemented on the basis of voluntary may affirm this statement. GDP also supports this fact. However will it be possible to achieve the same conclusion, if the number of companies is analyzed?

Tab.3 - The number of registered companies in relevant countries in 2005. Source: data of The World Bank

State	Total number of companies	Listed companies	Share
United Kingdom	2 160 200	2 759	0,13%
Canada	2 400 000	3 721	0,16%
Australia	616 196	1 643	0,27%
Russian	2 908 840	296	0,01%
Mexico	4 290 000	151	0,00%

It is obvious that the absolute number of traded companies represents only a fraction of all companies registered in the country. Individual shares are below half a percent. It must be borne in mind that it still may be felt the effects of the economic crisis although the current situation has given witness to its overcoming. This was also reflected in the number of companies traded on the stock exchanges. The United Kingdom is an obvious example with a downward trend in 2012 where 2179 companies were traded in December of that year compared to 2228 companies in the previous year resulting in a decrease by 2.2%. The difference is noticeable, if it takes into account 2913 traded companies in December 2006 (Turner, 2013).

The following Figure shows that the UK is not the sole affected country. Prevailing economic conditions adversely affect the whole developed Western world.

Fig.4 - The trend of number of listed domestic companies in the years 2002 - 2012 (world).  
Source: data of The World Bank

Because IFRS are primarily designed for companies that are traded on the capital markets, the decline illustrated above could affect negatively the extensiveness of their use. However, it is not appropriate to confirm this causality automatically. There is a certain inertia in many countries (emphasis on consistency of rules and methods) in accounting (in preparing the financial statements respectively) when the entity ceased to be traded. Even if this was not explicitly required by the relevant regulations, no authority (e.g. Ministry) has the power to enforce this entity not to follow IFRS voluntarily. The company itself has to assess the benefits and sacrifices to reporting under IFRS related (e.g. The reason for the continuity may be the fact that the company is a subsidiary and thus in a role of subordinate to a parent company or ceases to be traded temporarily but is going to return to the stock market in short time etc.).

Much valuable information is provided in the following table dividing data from the territorial point of view. Table tries to expand the Figure 4 in detail and identify proportions of the individual territories. As can be clearly seen the Asian exchanges have recorded continuous growth despite the crisis. There is no need to explain that the IFRS Foundation has aimed its attention to Asian area and to territory of emerging markets in general as one of the potential options how IFRS could continue to expand around the world.

Tab.4 - Number of listed domestic companies in WFE exchanges in territory perspective.  
Source: data of World Federation of Exchanges (WFE)

Territory	2008	2009	2010	2011	2012	2013
America	9 577	9 158	9 061	9 132	9 089	9 088
Asia-Pacific	20 356	20 421	20 905	21 529	22 488	23 048
Europe-Africa-Middle East	9 529	9 296	9 231	9 467	8 990	8 853
Total	39 462	38 875	39 197	40 128	40 567	40 989

Covering the scope of IFRS only by traded companies is quite confusing and distorted, although they represent the biggest share of entities reporting under IFRS. But the reality is more diverse because the jurisdictions themselves specified in detail (mainly extend) the requirement to report under IFRS to other entity. It can be seen from the global survey and its received questionnaires that the typical businesses (besides the traded companies) are unlisted:

- banks, insurance companies and other financial institutions,
- controlled entities (i.e. subsidiaries), and

- other (see below).

The relationship of the three mentioned groups to IFRS is relatively logical. For example, banks, insurance companies and other financial institutions are classified as public interest entities by the vast majority of countries. IASB understands their status by the same way. It is seen from the definition of “small and medium-sized entities” included in the IFRS for SMEs as well. The using of IFRS by controlled entities results from certain pragmatic approach trying to minimize the additional costs associated with reporting under the two (or more) accounting frameworks (the first required by the law and the second for the needs of the parent entity basically following either US GAAP or IFRS). The "other" means all remaining entities which are required to use IFRS as well if they meet certain legislative criteria. Those criteria are often determined by the size of turnover, value of assets and number of employees. They generally affect a limited number of larger entities. The legal form of company or the specific companies (mostly with majority of state participation additional) also represent the decisive criterion.

Figure 5 shows how many countries and for what types of businesses (entities) determine the mandatory use of IFRS. It can be seen that 109 countries required IFRS for listed companies. Relatively expressed, it represents almost 80% of all countries (respondents of IASB survey). A large part of countries has extended these requirements to financial institutions as well. However, there are also countries that require IFRS only for financial institutions, but generally not for listed companies surprisingly. Saudi Arabia and Uzbekistan represent this group. The obligation to report under IFRS for subsidiaries is only sporadic. Much more frequent situation is to allow IFRS as a possible alternative accounting framework.

Tab.5 - The number of countries requiring the IFRS with regard to company categories.  
Source: Self; based on IASB survey of jurisdiction profiles made in 2012

Category	Number of states	Share of total
Listed	109	79,56%
Financial institutions	64	46,72%
Subsidiaries	19	13,87%
Other	45	32,85%

This section has provided information how many and what types of companies use or have to use IFRS. Analysis of the absolute number of listed companies, for which IFRS are primarily intended, clearly shows that these entities represent only a fraction of all existing companies. The absolute number of companies included in remaining three groups does not spread the total figure of entities reporting under IFRS too much. Therefore, it is not correct to talk about IFRS as the global standards. However another dimension comes when these companies are expressed by their size in financial terms. This consideration describes the essence of things much better because the entities using IFRS are often key drivers of national economies (world economy respectively) and form their substantial part.

Fig.5 - The number of countries with obligatory reporting under IFRS in perspective of company categories and territories. Source: Self; based on IASB survey of jurisdiction profiles made in 2012

### 3.3 The size of companies measured by the market capitalization

How to grasp the scope of IFRS application from a quantitative perspective, which would sufficiently reflect the importance of these companies? The amount of turnover or recognized assets could help to express appropriate measurement but these variables do not cover comprehensively the company's position in the economy. Searched quantitative indicator must be able to identify the impact as comprehensive as possible. This means that it should include all matters that affect the widest possible range of interested users. Market capitalization (MC) expressed as the product of the number of shares issued and their current market prices could be such indicator, although it can be seen limitations and disadvantages of this.

The Figure 6 is trying to bring a synthetic answer to question how strong position IFRS has acquired. It is measured by market capitalization of listed companies in selected countries to the world's total market capitalization. Market capitalization is compared with global GDP in the next step. The term "selected countries" is patterned on Figure 5 with 109 countries requiring mandatory use of IFRS for listed companies. Thus, "market capitalization in selected countries" gives information about the total market capitalization of domestic listed companies. Therefore this number can offer financially-measurable estimate of the current extent of IFRS application on a global scale, which is based on relatively solid grounds.

The past six years, for which data has been available, it is seen that the market capitalization in selected countries (except anomaly in 2008) has stabilized at about 20 trillion USD. In relative terms, the world market capitalization has held a stable share around 41%. IFRS therefore do not constitute even half of global share. It is possible to assess the situation by a simple comparison with the relative figure based on the ratio of absolute numbers of countries

(109 countries of total 193 which is about 56.5% of countries), as unfavorable. Logical deliberation concludes that IFRS (in so far as possible) are implemented by the economically less developed countries. However it cannot be simplified like that. Of course, many world powers have adopted IFRS – e.g. Germany, Great Britain and France in the EU, as well as Russia, Canada and Australia. But there are a few powers not adopting IFRS. Unfortunately for IFRS these representatives are the US, China, Japan and India. Five of ten largest Exchanges (WFE) do not require IFRS for domestic companies (according to the relevant national legislation). It is talked about NYSE (USA) NASDAQ OMX, Japan EG, Shanghai SE and SIX Swiss Exchange with an aggregate market capitalization of 32,616 billion USD in 2013 (26,129 billion USD for the previous year respectively).

Tab. 6 - The biggest exchanges (WFE members) measured by market capitalization (bn. USD). Source: 2013 WFE Market Highlights

Exchange	2013	2012	% change
1. NYSE Euronext (USA)	17 950	14 086	27,43%
2. NASDAQ OMX (USA)	6 085	4 582	32,80%
3. Japan Exchange Group	4 543	3 681	23,42%
4. London Stock Exchange Group	4 429	3 397	30,38%
5. NYSE Euronext (Europe)	3 584	2 832	26,55%
6. Hong Kong Exchanges	3 101	2 832	9,50%
7. Shanghai SE (China)	2 497	2 547	-1,96%
8. TMX Group (Canada)	2 114	2 059	2,67%

Fig.6 - The relationship and progress of market capitalization and GDP in relevant years for quantification of IFRS using. Source: Authors' computation; based on data of IMF, WFE and the World Bank

#### 4 CONCLUSION

The analysis presented in our paper is significantly based on data obtained from the global survey that has been conducted by the IFRS Foundation since 2012. It can be considered as certain limitation of the paper because the paper does not include origin research made by the authors. However, we believe that our contribution lies on aggregation of the survey results that we assessed using several (there are three described in this paper) own criteria and consequently developed our opinion regarding global use and global perception of IFRS. The first criteria – the number of countries – may be varied depending on definition of use of IFRS. If the definition of use is equivalent to the “official implementation” (in any kind of extent – mandatory/voluntary etc.), then survey gives information about 116 countries using IFRS. If this figure is put into the ratio with the total number of countries (based on the number of the United Nations members which comprises 193 states), it concerns nearly 60% of the countries in the world. Conversion into GDP brings a similar result. A substantial part of total (world) GDP is constituted by the EU economy which is not too positive message. Much worse balance is underlined by the fact that mandatory use of IFRS by domestic listed companies is not applied in China, Japan, India and the USA (however, some of them are in a transition process). The absolute number cannot be found negative but unfortunately it is a key element in terms of GDP to be possible to talk about IFRS as global standards. Given that the active trading is typical for these countries and therefore the quality accounting framework is needed, so it is difficult by our opinion to identify IFRS as global standards, albeit other standards do not enjoy more privileged position.

Secondly, number of companies depends whether listed or all companies are considered. IFRS are with their complexity designed primarily for listed companies. Their number is, however, negligible in comparison with a huge group of all existing companies. In recent years the number moves below the 50,000 listed companies worldwide due to the now receding economic crisis. Relatively it is only a hundredth of a percent of all active companies. IFRS are often required even for the non-listed - notably the financial institution, subsidiaries or companies exceeding certain specified limits (e.g. the amount of assets, turnover or number of employees). But the total number of companies using IFRS would not be changed too much. However, this indicator is linked only with a minimum level of relevance. The absolute number is not decisive in this respect and therefore this paper does not evaluate the status of IFRS by this criterion.

Finally, if the size of companies measured by market capitalization is considered the analyzed values immediately receive another dimension. From the scant hundredths of percent (related to the absolute number of firms) analysis shows quite interesting and especially more relevant figures now. The value of the ratio of the domestic market capitalization of listed companies in countries where IFRS are mandatory for them and the world's total market capitalization oscillates around the level of 41%. In 2012 domestic market capitalization represented 21,500 billion USD in the respective countries. For comparison, in the same year the two largest US stock exchanges symbolized about 18,500 billion USD market capitalization. If we add to them further significant exchanges where IFRS are not mandatory required for domestic listed companies (Japan Exchange EG, Shanghai SE and SIX Swiss Exchange), then the value will increase to more than 26,000 billion USD. This simple ratio provides a solid answer that it is very difficult in our opinion to consider IFRS as global standards due to the fact that only a few major stock exchanges with their market capitalization exceed the IFRS current position measured by the same indicator.

## **THE IMPROVEMENT OF HUMAN RESOURCE CONTROLLING IN SELECTED SERVICE COMPANIES**

*Monika Ďugelová, Mariana Strenitzerová*

### **Abstract**

Productive and effective employees are essential for the functioning of the organization. Human resources can become the competitive advantage and organisations should use their skills and abilities properly. Due to underutilisation of human resource controlling we consider important to study its using in service companies. The paper analyses the possibility of human resource controlling improvement with methods: comparison, analysis, synthesis, induction and deduction. The aim of our paper is to analyse the current state of human resource controlling using in selected companies and to identify the possibilities of improvement. Selected companies need to use complex human resource information system, to obtain the access to operative data for companies' managers, to periodically evaluate measured indicators and to measure more qualitative indicators. Our paper is important for future work and the results can be use also in other information technology companies.

*Keywords: Human Resource Controlling, human resource indicators, motivation, Data Envelope Analysis method, job satisfaction, employee productivity, employee efficiency*

### **1 INTRODUCTION**

In the current turbulent times the companies (manufacturing or service) want to optimize the using of resources, to decrease the costs and to achieve the competitive advantage. They should not forget about human resources – employees which are most valuable assets and also the source of competitive advantage.

Human resource controlling provides to human resource managers multiple benefits, but the usage is spread mostly in manufacturing companies. Because of universal character and strategic tendency we decided to implement human resource controlling in tertiary sector.

We analysed the choice of SK NACE section J – Information technology and communication in the previous work (Dugelova & Strenitzerova, 2014b). Also the definition of problems with implementation in IT companies was defined in our previous work (Dugelova & Strenitzerova, 2014a).

To follow on previous studies the aim of our paper is to define the possibilities of human resource controlling improvement in selected service companies and to propose solutions for lacks in used tools, human resource indicators and in human resource information systems. We focus primarily on four selected (different size) information technology companies. Our study can help understand information technology employees, their performance and their management. The paper forms the basis for further studies and for creating universal methodology of human resource controlling implementation in different IT companies.

There is no extensive research examining the practical issues of human resource controlling. From Slovak authors we use the work of Majtan (2007), Olexova (2011) and Strenitzerova (2010). From Czech authors we would like to mention the work of Dvorakova (2007) and Busina & Sikyr (2014). From Poland authors we work with the paper from Laskowska

(2010). General controlling and human resource controlling is widespread only between German authors' work (e.g. Hentze & Kammel, 1993; Lisges & Schübbe, 2004; Wunderer & Jaritz, 2007; Wütscher, 2006; Dilger, 2005; Dilger et al, 2005; Scherm & Pietsch, 2005). All of them defined the theoretical basis of human resource controlling and the importance of appropriate tools. Busina & Sikyr (2014) solved the problem of human resource controlling in small and medium size companies in building industry. They described the human resource management in the companies and its general characteristics. Laskowska (2010) solved the usage of human resource controlling in Polish libraries. She surveyed library employees to find out the level of motivation and satisfaction with working conditions and she used SWOT analysis to define lacks in human resource management. But Busina & Sikyr (2014), Laskowska (2010), Slovak or German authors did not define the detailed methodology of human resource controlling implementation. For primary research we can use only report Human resource controlling 2013 from PricewaterhouseCooper and German website [www.controllingportal.de](http://www.controllingportal.de).

## **2 THEORETICAL BASIS**

Human resource management and human resource department employees work with control to test employee performance and to find out the level of performance appraisal system. Control can be defined as any process that helps align the actions of individuals with the interests of their employing firm. (Tannenbaum, 1968) The human resource control is not the same as human resource controlling. Control is oriented on the past, controlling is oriented on the future. Main aim of control is to determine an error, aims of controlling are: to plan, to control and to correct mistakes. Controlling also helps to guide and inspire while control only help to remove mistakes and their causes. (Laskowska, 2010)

Fiedler (2011) defines human resource controlling as a management subsystem with main aim to support the company's management. All in the terms of management oriented approach. Controlling helps with the coordination between planning, control, organization, personnel management and information supply. Human resource controlling is than the specialization of general controlling. It differs from the general controlling in its functions (Schäffer & Webber, 2005):

- control and coordination of information flows in human resource management,
- preparation of human resource related decisions by analysing the information provided by and about the employees and
- monitor implementation of the human resource department decisions.

Human resource controlling represents the application of controlling conceptions on the level of human resource management (HRM) as a strategic company's field. Human resource controlling is a controlling of functional area and its role is planning, checking and managing including information supplement for selected functional area. It deals with concretization of short-term and long-term objectives of HRM and with the assessment of their achievement. (Milkovich & Boudreau, 1993; Majtan, 2007)

Human resource controlling deals with the concretization of operational and strategic objectives of human resource management and with an evaluation of their achievement. Olexova (2011) defines human resource controlling as a company's strategic tool. It is important to set objectives, to obtain information about planned and actual level of human resource processes, to find the deviations and to design measures to eliminate shortcomings. (Strenitzerova, 2010)

Dvorakova (2007) uses for the human resource controlling definition the general controlling definition. Controlling is a managerial tool that increases the company's value, involves in the budget and financial plan creation and in eliminations of deviations.

The human resource controlling functions are done by controller. Niedermayr-Kruse et. al (2014) characterise controller as a partner of manager that monitors every process and tries to optimize and save costs.. The main controller's task is to manage the process of human resource activities with human resource indicators, to monitor and evaluate them and to take corrective actions based on found deviations. According to Potkany (2007) this process can be divided into three activities:

- definition of HR objectives,
- monitoring and evaluation of their achievement,
- transparency in human resource function and its approach to customers' requirements.

Potkany also highlighted the importance of objectives set by human resource controlling. They would follow the company's strategic objectives, explicitly define the benefits of human resource management, be specific and set the penalty for failure. (Mihalcova, 2007)

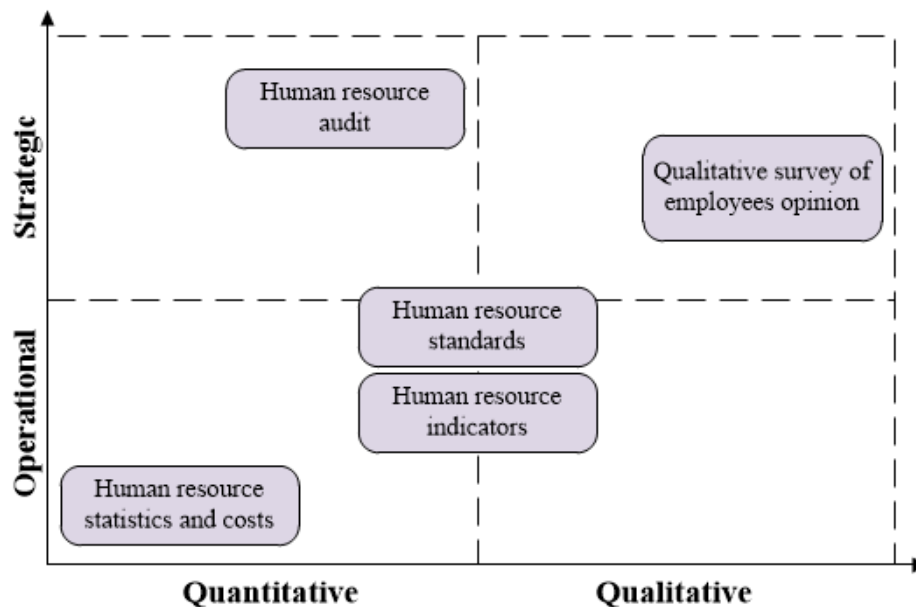

Fig. 1 – Human resource controlling tools. Source: Olexova, 2011

Human resource controlling acts with multiple controlling tools (see Figure 1). Their dividing is based on the strategic/operational view and qualitative/quantitative aspect. The most popular tools according to Olexova (2011) are human resource audit and human resource indicators. The qualitative indicators are difficult to measure and the results are not so explicit but HR managers would not omit them. An interview with employee or the human resource standards can help to find the gaps and improve the HR efficiency.

Website [www.controllingportal.de](http://www.controllingportal.de) recommends these human resource controlling tools: human resource scorecard, human resource due diligence, human resource potential analysis, target-performance comparison, SWOT analysis, risk-reward analysis and portfolio matrix.

Jungmeister (2005) promote other tools. In quantitative tools they include: key human resource indicators, score cards and initiatives to decreasing human resource costs. In

qualitative tools they include: assessment of employees personal development, human resource surveys, SWOT analyses and development scenarios.

Olexova (2011) adds other less used tools: HR benchmarking, model excellence EFQM, methodology Process Survey Tools, the concept of indicators (KPI – key human resource indicators, PI – human resource indicators, KRI – key result indicators) and Balanced Scorecard.

### **3 METHODOLOGY**

Human resource controlling in service companies depends on special characteristics of service companies. Horvath (2004) helped to implement controlling in several service companies and identified main problems of potential successful implementation. Horvath (2004) describes controlling in trading company, in insurance company, in banks, in public administration and in non-profit organisations. The common elements of all branches are:

- problematic accounting of services,
- problematic measurement of employee's work,
- the service sector is dominated by almost invisible inputs and outputs.

Selected service companies are included in information technology and communication branch (according to SK NACE – section J Information and Communication). After practical research we can identify following problems with controlling implementation: problematic measurement of developer's work (developer performance does not depend on the code length but on the quality and utilization for project), the lack of qualified applicants, the matrix organizational structure and project management (this allows employees to participate in more projects and to obtain multiple subordination), the lack of communication and problems with coordination between managers. (Dugelova & Strenitzerova, 2014a)

To gain paper's objective "The definition of the improvement possibilities of human resource controlling in selected service companies." we surveyed four IT companies in Slovak republic. The survey was conducted from June to December 2014. The companies did not wish to publish their names. All companies work in section Information and Communication. Company A has over 60 employees, company B has over 400 employees, company C has over 1.000 employees and company D has over 2.700 employees. Our survey consists of two expert interviews divided into five parts: basic information, human resource department work, human resource controlling tools, human resource information system and possibilities of future human resource controlling development.

To deal with mentioned problems we chose following methods:

- comparison of human resource controlling tools,
- analysis of using human resource information system and following synthesis to gain new insights,
- comparison of human resource indicators (as human resource controlling tool used in all selected companies),
- and induction and deduction to generalise obtained results and to propose appropriate solutions.

## **4 RESULTS AND DISCUSSION**

To generalise the methodology of human resource controlling we use the paper from Horvath & Partners (2004), the recommendations from [www.controllingportal.de](http://www.controllingportal.de) and report Human resource controlling 2013 from PricewaterhouseCoopers. Effective human resource controlling needs appropriate human resource controlling tools and their correct and full utilisation. The tools need to be selected according to human resource vision, human resource processes and human resource controlling aims. All human resource controlling tools need proper data and this data are obtaining from human resource information system. Used human resource controlling tools and various aspects of human resource information system were surveyed in all four selected companies. These characteristics are also later recommended for improvement.

### **4.1 The usage of human resource controlling tools**

The percentage of human resource controlling tools using (see Table 1) was consulted with human resource managers and human resource controllers. They defined the utilisation of the most popular human resource controlling tools (defined by Olexova, 2011). The utilisation is expressed with the percentage of the maximum possible using. We use the scale:

0% = human resource controlling tool is not used

1 – 25% = human resource controlling tool is hardly used

26 – 50% = human resource controlling tool is not used very often, more than a half of functionalities are missing

51 – 75% = human resource controlling tools is used, some specific functionalities are missing

76 – 100% = human resource controlling tool is used, complex evaluation is missing

100% = human resource controlling tool is fully adopted and used

Human resource controlling in company A is based on tools: human resource indicators and qualitative survey of employee opinion which are almost fully used. Human resource audit is performed only as one part of complex company audit and human resource standards, statistics and costs are not used very often. Company B uses the full potential of two tools: Human resource standards and Balanced Scorecard. There is a significant using of qualitative surveys and human resource indicators, other tools are not used very often or very detailed. Company C has fully adopted tools: human resource indicators and Balanced Scorecard, other tools do not have significant results. Human resource controlling in company D is based on human resource audit and human resource standards. Human resource indicators are almost fully used; operative access for lower management is missing. Human resource statistics and costs are not fully adopted.

The human resource indicators are adopted and used in all selected companies. Percentage of using is above 70%. The indicators are also the most important human resource controlling tool for the analysis of current situation in selected companies. It is the cornerstone of human resource controlling. The process of using human resource indicators for human resource controlling consists of the following parts: indicators identification, target results identification and regular monitoring of deviations. The human resource indicators are included between operational tools but they reflect strategic aspects and the quality of human resource management. The resources of human resource indicators data are human resource administrations and payroll accounting. Properly chosen human resource indicators can be used in benchmarking and they show the long-term company development. (Olexova, 2011)

To identify the measured human resource indicators we use the report Human resource controlling 2013. The report divides human resource indicators into seven groups: corporate results, remuneration and employee benefits, behaviour within the organization, training and development, talent management, recruitment and selection and organizational structure. The list of measured indicators is in Table in attachment. We can see selected companies and their HR managers and HR department employees use mostly quantitative human resource indicators. They focus on costs and return on investment and indicators gain from human resource information system (salaries, employee number and structure, training hours, statistics about organizational structure and fluctuation). (Pavlik, 2014)

These indicators should be periodically monitored, evaluated and presented to top management and other interested parties. But only company C has fully implemented tool human resource indicators (we can see it also in Table 3). The indicators are measured, recorded by human resource information system and periodically evaluated. The results and indicator's time evolution are presented during the meetings and by human resource controlling intranet application. The example of selected human resource indicators evaluation in company C is shown in Table 2. We can see only evaluation of quantitative indicators, which are easily compared. The qualitative human resource indicators are not the part of this report. This report contents the results in year 1 and 2 and planning results in year 3. This data is important for strategic plans and managerial decisions.

√ positive evaluation

↓ negative evaluation

Qualitative indicators are not used in all companies. The selected companies carry out the qualitative survey to determine employee satisfaction and their opinions on company's performance. The survey results are not fully included in HR controlling indicators. Selected companies use these qualitative indicators:

- degree of satisfaction with the salary,
- employee satisfaction within the organisation,
- employee satisfaction with the company performance,
- reasons for leaving the job (companies A, B, D).

Satisfaction degrees are based on employees' answers in Likert-type scale (from very satisfied to very dissatisfied) and these results are not statistically evaluated. The human resource manager or responsible human resource department employee reports comparison of answers to top management and creates solutions or corrective actions in case of decreased satisfaction.

The results of monitored qualitative indicators do not show the performance level and do not answer the questions of motivation level and the relation between these variables. As we previously mentioned the biggest problem in IT companies is measurement of developers' work and relations to motivation and employee satisfaction with occupations and within the company. The possible solution is creation of one indicator that includes all qualitative factors of employee performance. To gain this resolution we test the DEA (data envelopment analysis) method and its using in IT companies. Our DEA indicator integrates employee satisfaction with salary, working conditions, motivation, managerial approach and manager satisfaction with employee and his productivity. This survey is in progress and we will inform about the results in our future works.

#### 4.2 The usage of human resource information system

Human resource information system (HRIS) is designed to assist the human resource and payroll departments in the performance of their overall employee management function. According to Badgi (2012) HRIS contains of IT software and systems that are associated with managing employee data, overall life cycle of employee, benefits administrations, leave management, talent management, payroll and related HR functions. The success of human resource controlling and its tools depends on data obtaining from human resource information system.

Tab. 3 – The important aspects of human resource information system in selected companies.

Type of using information system	Commercial human resource information system	Excel sheets made by human resource manager	Custom-made human resource controlling information system	Custom-made human resource controlling information system
Responsible person	Human resource manager	Human resource manager	Human resource controlling manager and human resource controlling department	Human resource controlling manager and human resource controlling department
Top management access	During the meetings and company's results presentation	During the meetings and company's results presentation	Access via the human resource controlling application	Access via the human resource controlling application
Middle management access	During the meetings	During the meetings	Access via the human resource controlling application	Access via the human resource controlling application
Lower management access	on request	During the meetings	Access via the human resource controlling application	on request

Surveyed companies use different types of human resource information system (see Table 3). Company A uses two basic modules of commercial HRIS Hour (employee data and payroll) and responsible person is human resource manager. Human resource manager informs other company's managers (top and middle management level) about the important results during the meetings and company's results presentation. Lower managers obtain human resource controlling results on request from human resource manager. In company B human resource manager uses as information system custom made excel sheets. The results are available only for human resource manager and he presents the results to other managers during the meetings and other presentations. Company C and company D have custom made human

resource controlling information systems. These information systems operate as OLAP (online analytical processing) models. Employees of human resource controlling department are responsible for data and results evaluation. Selected results are available for other managers via human resource controlling intranet application. In company C managers of all levels have access to intranet application. In company D only managers of top and middle level have access to intranet application, lower managers gain data on request from human resource controller.

## **5 CONCLUSIONS AND RECOMMENDATIONS**

The survey in four selected IT companies shows us the differences between the human resource controlling levels. After the comparison of companies and theoretical and practical work of other authors we can identify the possibilities of human resource controlling improvement. The human resource controlling in IT companies deals with the problematic measurement of employees' work and with multiple subordination. To eliminate the problems and to improve human resource controlling we recommend these solutions:

The company A with only 60 employees does not have resources for big changes. We recommend focusing attention to two human resource controlling tools: human resource indicators (the most important tool) and qualitative survey of employee opinion. The results of qualitative survey will be the part of human resource indicators. They will be archived to obtain the basement for comparison and time evolution analysis. Human resource information system is appropriate used; we recommend buying more modules (education and training) and create the access for management.

The company B disposes of resources to change human resource controlling and human resource management significantly. The biggest problem is inadequate human resource information system. Excel sheets made by human resource manager are appropriate in small companies. The company with 400 employees needs more complex and robust information system. The solution is buying the commercial HRIS or making own human resource management and human resource controlling information system (as in company C and company D). The improved HRIS will optimize the human resource indicators using. The usage of tools: human resource standards and Balanced Scorecard is appropriate. The company can think about the change to other tools only in case of changing company's vision and human resource strategy.

The company C achieved the best results in our survey. HRIS is fully adopted and used; managers of all levels have access to information system and operative results. The only lack is in using the tool "Qualitative survey of employee opinion". It is needed to conduct survey two times per year, including all important aspects of employee satisfaction and evaluate results. The human resource indicators were chosen according to human resource management strategy five years ago. The human resource controller should take into account current issues and change measured human resource indicators.

The company D has the similar problem as company C. HRIS is fully adopted and used by human resource controlling department and managers of top and middle level. Lower managers obtain results on request. The improvement is necessary in access of lower management and in using of qualitative surveys. Other human resource controlling tools are used sufficiently. The change of preferred human resource indicators tools would be necessary after change of employees' organisation or human resource controlling aims.

To generalise our recommendations it is important for IT companies take into account these facts:

- the success of human resource controlling depends on data relevance and data relevance depends on implemented HRIS and its functionalities,
- OLAP system is more appropriate than relational database for human resource controlling information system (relational database is not appropriate for nearly immediate analysis and displaying a big amount of data),
- the most using human resource controlling tools are: human resource indicators, human resource standards and qualitative survey of employee opinion,
- it is important to provide operative results access for managers of all levels (in bigger companies),
- human resource controlling intranet application is appropriate solutions of data obtaining,
- human resource controllers and other responsible persons need to periodically monitor and evaluate important indicators and solve obtained deviations with managers.

Our recommendations for improvement can be used in all IT companies and also in similar service companies. We gain paper's objective: "The definition of the improvement possibilities of human resource controlling in selected service companies." and our survey is first step for following work. Future work will investigate the selection of human resource indicators in IT companies and we will prove our draft in practise. We also investigate the using of DEA method as qualitative indicator and the relation between productivity and the change of individual inputs and outputs. Another study can also focus on the possibility of using IDEA method and on the differences between DEA and IDEA (Imprecise Data Envelopment Analysis). IDEA requires that the number of employees should be at least 30 times higher than the total number of input and output and this condition is fulfilled only in company C and D.

## **DETERMINANTS OF INNOVATION IN SMALL AND MEDIUM ENTERPRISES**

*Marek Ehrenberger, Evgeny Lisin, Wadim Strielkowski*

### **Abstract**

This paper investigates the determinants of innovation in small and medium enterprises (SMEs) in the Czech Republic. The country that has undergone painful economic transformation and institutional change leading to the establishment of the new standards of entrepreneurship is now dealing with the aftermath of world's economic crisis. Czech SMEs strive to survive in the tough competition on domestic and EU markets and innovations might become one of the ways how to differentiate their product and outrun the competition.

Our case study is based on the survey questionnaire with 1144 Czech SMEs. We find several significant determinants for innovation: own R&D, investment into technology, improvement of quality of a product or service, or presence on foreign (EU and world) markets. Moreover, bureaucratic barriers for innovations and external factors with negative impact did not come through as significant obstacles for innovative activities in SMEs.

*Keywords: innovations, SMEs, transition, Czech Republic, economic crisis*

JEL Classifications: L25, P36, R10

### **1 INTRODUCTION**

Small and medium enterprises (SME) are thought to be best suited to take advantage of opportunities on the market, as far as they possess the capacity to survive, grow and retain a competitive advantage (see e.g. Nooteboom, 1994; Shane & Venkataraman, 2000; Hayton, 2005; Steyaert, 2007; Felício et al., 2012; Klyver, et al., 2012; or Malbašić & Brčić, 2012).

At the beginning it is important to define the concept of innovation and its multiple types. Edwards and Gordon (1984, p. 1) define innovation as "a process that begins with an invention, proceeds with the development of the invention, and results in the introduction of a new product, process or service to the marketplace". This definition looks at innovation as a rather technological perspective (Dubini, 1988). The issue is that not every innovation begins with an invention. Many innovations take a form of an improvement (Dodd et al., 2007).

Innovations play an indispensable role in everyday activities of today's society, spanning across all areas of our lives. They are especially important in technical and economic disciplines. Whereas they are a key to progress in the former one, they are an essence of success or failure for the later one. Innovative activities have become an important aspect of every economic or scientific activity, because they create new space for potential specialization and future growth (Feldman & Audretsch, 1999). They allow us to push limits further and the new quickly becomes the standard. In the ever more globalized and interconnected world they are a necessity rather than an option for firms if they want to survive and grow further. Thanks to their creative nature they embody positive benefits both for their inventor and their user. The inventor usually earns a reward in a form of money or respect (Hughes, 1992; or Sorensen, 2007). The user then gets a result with improved quality, availability, diversity or increased quantity.

The question is whether small or large firms are better suited to bring the desired goals of growth, employment and competitiveness and whether innovation is something that can significantly improve chances of firms to achieve success. This paper argues that small and medium sized businesses and especially their innovative activity are capable of and well suited for pursuing such desirable goals.

Innovations play an indispensable role in everyday activities of today's society, spanning across all areas of our lives. They are especially important in technical and economic disciplines. Whereas they represent a key to progress in the former one, they are an essence of success or failure for the latter one. Innovations became an important aspect of every business activity due to the fact that they can create a new space for potential specialization and future growth. In addition, they allow pushing up the boundaries. In the ever more globalized and interconnected world they represent a necessity rather than an option for firms if they want to survive and grow further. Thanks to their creative nature they embody positive benefits both for their inventor and their user. The inventor usually earns a reward in a form of money or respect. The user then gets a result with improved quality, availability, diversity or increased quantity of goods and services.

## 2 SMEs IN THE CZECH REPUBLIC IN ECONOMIC TRANSITION

SMEs constitute a backbone of the Czech economy both in microeconomic and macroeconomic realm (see Earle et al., 1994). Kočenda et al. (2004) or Hanousek & Kočenda (2004) note that small firms in Czech transition were the main cause of low unemployment and accounted for the majority of newly created jobs. They conclude that the retained profit of small firms was a major determinant of new investments.

In order to provide an overview of the current state and the development of Czech SMEs since the EU accession in 2004, we present an overview of the structure of active economic subjects in the Czech Republic according to the employee categories (Tab. 1).

The numbers reported in Table 1 are not for all registered subjects (which are about twice as high but for all active entrepreneurial subjects due to the fact that these data are more meaningful (CZSO 2007)). Active entrepreneurial subjects are classified according to the data obtained by statistical surveys, tax returns and payments for social insurance and thus give at least some lead of economic activity.

Tab. 1 – SMEs in the Czech Republic. Source: CZSO (2011)

Year	Total active subjects	Categories according to the number of employees											
		Not specified	Without employees	1 - 5	6 - 9	10 - 19	20 - 24	25 - 49	50 - 99	100 - 199	200 - 249	250 - 499	500 - 999
2005	1 266 336	277 271	733 249	169 922	28 137	26 129	6 356	12 015	7 211	3 394	639	1 163	540
2006	1 256 771	262 296	723 796	183 214	28 473	26 850	6 401	12 138	7 386	3 492	649	1 188	557
2007	1 224 863	302 601	647 818	185 007	29 346	27 267	6 579	12 393	7 473	3 545	691	1 227	579
2008	1 345 589	284 251	780 260	188 734	30 383	28 208	6 845	12 639	7 787	3 599	702	1 236	581
2009	1 346 185	253 963	817 540	183 855	30 316	27 903	6 433	12 454	7 519	3 477	662	1 188	523
2010	1 399 983	281 109	841 562	187 674	29 856	27 258	6 179	12 529	7 473	3 514	669	1 218	584
2011	1 461 201	319 639	862 087	191 302	29 064	26 686	5 991	12 664	7 421	3 506	621	1 242	612

Figure 1 provides information on the total number of active economic subjects and its development over years.

Fig. 1 – Economic subjects in Czekia to total population (2005-2011). Source: CZSO (2011)

The total number has been growing slightly, around 2.4% per year. Likewise, the birth and death rate of economic subjects shows a relatively stable development (Figure 2).

Fig. 2 – Births and deaths of economic subjects in the Czech Republic (2005-2011). Source: CZSO (2011)

Although it includes subjects of all sizes, we can assume, according to above mentioned proportionality, that it represents mainly SMEs. The average birth rate between 2005 and 2011 was 110 101 subjects a year. The average death rate, influenced by a sharp increase in 2009, was 59 229. Without this peak year it is relatively stable 52,289. The increase in the death rate was caused by the economic crisis which caused the Czech GDP to decrease by 4.7% (CZSO 2012) and the unemployment to rise from 4.4% to 6.7%.

Czech SMEs provided employment for over 1.8 million people in 2010, a 60.88% share on total enterprises. Since 2007, when the number peaked at over 2 million, this is a 10% drop (CZSO 2011). In 2009 and 2010 SMEs saw return of their revenues to 3.9 billion CZK and the total revenues were steadily growing since 2000 till 2008 when the economic crisis struck. The economic crisis and the recession brought a significant drop to all SMEs financial indicators.

One of the most important indicators of SMEs' economic activity is their role in international trade (see e.g. Arslan & Karan, 2009). It is good to know how SMEs are doing, especially in the context of the new export oriented strategy crafted by MIT (2012) which has increasing the number of exporters among SMEs by 50% as one of its priorities.

This strategy puts emphasis on exports to territories outside Europe, which means that SMEs will eventually be forced to compete globally. So far, their share on total Czech exports in 2010 was 51.3%, amounting to 1.29 billion CZK.

Fig. 3 – Czech SMEs in international trade. Source: CZSO (2011)

This number is steadily growing since 1997 (Figure 3). The number has more than doubled between 2004 and 2001. The gap between exports and imports has been shrinking over time, from almost 35% to little above 4%. This is a clear sign that Czech SMEs are able to withstand competition on the foreign markets.

### **3 SMEs INNOVATION: QUESTIONNAIRE SURVEY APPROACH**

In order to identify the determinants of innovations in Czech SMEs, we collected 1144 online questionnaires and obtained detailed firm-level data on firms' characteristics and innovations. Our complex dataset contains a wide range of indicators covering both SMEs' internal and external characteristics, such as a number of employees, structure of ownership, sources of innovations or their barriers, number of competitors, size of operated market and influence of the firm's environment on its actions. The outcomes thus bear valuable information about specific factors that may ultimately lead to innovations. Thanks to the extent of the dataset the right factors influencing innovative activities of firms can be identified and further evaluated in an econometric model.

The aim of our survey was to obtain as much reliable information from SMEs as possible. Two crucial problems emerge when trying to collect such data in reality. The first one is the difficulty to find someone who would be willing to provide such specific data; in case he actually had them. The second problem builds on the first one: even if a firm was willing to provide the data, it could be extremely difficult to extract them in sufficient quality, because no firm has a reason to spent resources on tracking specific aspects of innovations. This is especially true for SMEs, and so the questionnaire was designed to ask simple questions that can be answered quickly and without any research in firm's books.

Searching for contacts to firms was the first step towards having a sufficient amount of potential respondents of our online survey. The Magnus Web database (Čekia, 2011) was used to gain email addresses to approximately 49 thousand firms in employee categories from without employees to 200-249 employees.

Fig. 4 – Geographical spread of the surveyed enterprises. Source: Own results

The survey consisted of 21 questions and was designed with the help of a specialized online survey server. The questions in the survey were short and ready to be filled with just one click, making the answering process relatively easy and fast. The average time spent with answering our questions was around 11 minutes. Figure 4 shows the geographical distribution of the surveyed enterprises. Although the majority of them originated from Prague (25%), the rest were evenly distributed around the country. Figure 5 reports the main areas of business of surveyed enterprises. The majority (20%) operated in manufacturing. This was followed by 17% and 16% of enterprises operating in construction and wholesale and trade respectively.

Fig. 5 – Main business activity of the surveyed enterprises. Source: Own results

The majority of firms in the sample (48%) had less than 9 employees, 3% had in between 100 and 199 employees and 1% had between 200 and 299 employees. Figure 6 reports the turnovers in surveyed enterprises in the three consecutive years (2009-2011).

Fig. 6 – Turnover of the surveyed enterprises. Source: Own results

Figure 7 depicts the dynamics of distribution of sales for surveyed enterprises in our sample with respect to local, national, EU and world markets in the three consecutive years. This information is of a special interest, since it reflects the link between innovations and sales spread.

Figure 8 reports licenses, patents or awards. Other answers included plenty of specific certificates, prizes, trademarks or industrial patterns. A few firms are in preparation phase for ISO certificate.

Fig. 7 – Distribution of sales of the surveyed enterprises. Source: Own results

Some firms expressed their mixed or negative experience with ISO certificates. This may be caused by the fact that obtaining a certificate can be a bureaucratic burden for a small firm or that it is of no use for the entrepreneur. Only a small number of firms belong to a cluster and 13% of them do not know whether they belong to such a structure.

Fig. 8 – Certificates, patents and licenses of the surveyed enterprises. Source: Own results

The majority of firms compete in price (for the majority of firms (44%), there are between 5 and 25 main competitors in their area of business) (Figure 9).

Fig. 9 – Main areas of competition of the surveyed enterprises. Source: Own results

Many firms noted that there was often unreasonable pressure on price at the expense of quality. Proportion of firms competing in quality and product innovativeness also confirms that finding. However, competition in prices pushes margins down and inhibits so much needed investment into development of new and better products or services.

#### 4 EMPIRICAL MODEL AND ITS PROVISIONS

The aim of this model is to identify determinants of innovations in SMEs. After thorough evaluation of the theory behind innovations, intensive collection of a large amount of data and careful finalization of the dataset, we will now proceed to description of the model and later to its estimation. The linear econometric model used in our paper is a multivariate statistical model of the form:

$$Y = \beta_0 + \beta_1 X_1 + \dots + \beta_n X_k + \varepsilon_i \quad (1)$$

where Y is the dependent variable defined as the enterprise profit per employee in 2004,  $X_1, \dots, X_k$  are the explanatory variables and  $\varepsilon$  is the error term.

The results of our estimations are conditional on a set of specification and diagnostic tests. First, heteroscedasticity test was run and heteroscedasticity was detected. Therefore, robust standard errors were used.

Number of innovations according to categories was selected naturally as an explained variable. Dependent variables for the final model have been carefully chosen during the process of crafting a solid model reliably identifying the key determinants of innovations. Just eight observations had to be taken out of the model, because they did not contain information on number of innovations the firm has achieved.

Overall, four models (innovation model, ownership model and impact factor model with robust standard errors and barriers model using OLS) were estimated using Gretl statistical software. They used 1136 observations, consisting of seventeen variables, three of which were categories and the rest binary variables. Table 2 reports the results of all four models in question.

It appears from our analysis that enterprises classified as small or medium ones tend to be more innovative than micro enterprises. This can be explained by their relative abundance of financial and human resources. Some of them can be specifically devoted to developing new products or service, while micro enterprises (often represented by sole traders) do not have this option.

Moreover, it becomes apparent that larger target markets induce more innovations. This relationship could be also viewed from the other direction, namely that innovation causes the firm to expand territorially. These two links cannot be simply separated because they occur simultaneously. Innovations enable the firm to compete internationally and at the same time international market puts more pressure on innovativeness of the offered good.

Quite surprisingly, in the case of Czech SMEs, licenses did not come through as significant determinant of innovation. This might be explained by their diversity and real impact on firms. This finding supports the argument that patents may not be a good representation of innovations which was discussed in section 3. On the other hand, belonging to the cluster plays a positive role (which is in accord to similar findings from other countries – see e.g. Van Zyl & Mathur-Helm, 2007; Navickas & Malakauskaite, 2010; Hovelja et al., 2010; Stephens & Onofrei, 2012; or Conway, 2012). Small firms in the clusters dominated over those that were not aware of the advantages that clusters provide, especially in terms of synergy.

Our findings show that increasing age of equipment is negatively related to innovations. This is quite understandable, as far as the newer equipment allows more innovative usage and implementation. On the contrary, competition had a positive effect (especially higher competition categories). It might be that more competitive environment forces firms to innovate more. However, a top innovative firm with a unique business proposition can have very few competitors. There are also firms that specialize on serving the public sector and if selected in often dubious public procurements, these firms no longer have motivation for improvements in the absence of any competitors (see e.g. Alexandrova, 2012).

A number of investing activities of firms show significant impact on innovations. Investments into technologies and quality show a strong impact, also when compared to other variables. Although investment is just a precondition to a potential discovery and its successful realization, it is a necessary step towards achieving innovation. Unfortunately, our survey revealed that many firms could not afford to invest because their main concern was survival on the market. This creates a vicious circle because without investment innovations have a harder way to come and nobody can expect high profits for mediocre goods or services.

By far and large, the greatest determinant of innovations is own R&D which was indicated as a main source of innovations by 31% of firms. Although own R&D facilities may be a costly investment, it is definitely worth to have it. It is important to emphasize that not only medium firms exploit its benefits. About 30% of micro and small enterprises engage in this activity, followed by 41% of medium enterprises. Customers also represent an important source of innovations. This stems from the fact that they may come to the firm with new and more difficult requests and thus motivate it to higher originality.

Barriers to innovation did not prove to constitute a real obstacle for innovations to a large extent, although two actual barriers emerged nevertheless. Market barriers, e.g. competition or insufficient demand, and cooperation with scientific institutions thus had a negative effect on those firms who encounter them.

The legal form of the enterprise is also a factor crucial for innovations, as far as limited companies tend to innovate more than the other legal forms. This finding generally means that the limited company is the right form of enterprise for Czech SMEs nowadays.

## 5 CONCLUSIONS

Our paper provides an overview of factors that influence the innovation in Czech small and medium enterprises in the times of economic crisis. Results based on our empirical analysis tend to be valid for reasonable understanding of firms on a sectoral or regional level. However, when it comes to the micro level of individual firms, it turns out that every case is unique and no common inference can be easily drawn.

Speaking about the limitations of our research, one can mention that that our model was constructed in order to reveal important factors that have a solid impact on innovations in SMEs. Most of the factors can be influenced by the firm itself, it is therefore desirable for the firm to focus on them. At the first sight, some of them may look unsuitable for a particular firm, probably because the terms are used mainly in different context, i.e. R&D for non-technical firms providing services. It is important for every firm to translate these variables into its own language and find ways how to exploit the available opportunities. What can mean a new factory for one firm, can be a better software for another. Investments of different kinds have proven to work and deliver innovations. Firms should always find ways how to invest, even if it will not be large sums of capital. Even optimization of processes within the firm will be a good step forwards. Firms should not put too much weight on barriers or external environment as these have not emerged as real inhibitors to innovations.

It becomes apparent that the Czech government should focus on specific aspects of support for SMEs in the areas, where its guiding hand is really needed. In the Czech context, it might be the support of investment activities of SMEs, education of employees, expansions of Czech exports to the new markets and intensive support of R&D in firms that are the right subjects for that. Those firms have the potential to bring fruits in the future in the forms of productive innovations. General governmental support should create a progressive environment which would enable micro enterprises to grow faster to become small and medium enterprises that tend to be more innovative.

**DEPRECIATION INFLUENCE OF FIXED ASSETS  
ON ACCOUNTING RESULT AND CORPORATE INCOME TAX BASE  
PURSUANT ACCOUNTING AND TAX LEGISLATION  
IN THE SLOVAK REPUBLIC**

*Alexandra Ferenczi Vaňová, Renáta Krajčirová, Ivana Váryová, Iveta  
Košovská*

**Abstract**

Fixed assets represent the essential item of assets. Their higher level of wear and tear emphasized the need for asset renewal. The level of wear and tear of fixed assets is expressed by depreciation depending on the accounting measurement of assets, its predicted useful life and the application of depreciation method. Depreciation is not a part of sources of assets recovery from the accounting point of view. Accumulated depreciation is created by means of assets depreciation. It makes the asset measurement more realistic. Depreciation charges arisen from depreciation influence accounting profit or loss. Accounting depreciation is relevant for the compilation of cost calculation and therefore is a part of output measurement. Depreciation is considered as a source of internal asset financing, but generally is not sufficient for its entire renewal. The restricted possibility of investment renewal prolongs the use of depreciated assets which is reflected by costs of repairs and maintenance. The scope for the calculation of corporate income tax base presents disclosed accounting result before taxes which is adjusted by items increasing or decreasing corporate income tax base out of the accounting books. Applied tax depreciations of fixed assets are considered as tax costs.

*Keywords: fixed assets, accounting depreciation charges, tax depreciation charges, depreciation method, accounting result, corporate income tax base*

## **1 INTRODUCTION**

Fixed assets are depreciated in the reproduction process of an accounting entity. Cash expression of assets wear and tear represents depreciation while assets are depreciated from two points of view, state Bojňanský et al. (2013). From the accounting point of view assets are depreciated as regards their wear and tear pursuant current conditions of assets usage. Accounting depreciation represents costs influencing accounting result but not influencing the corporate income tax base. From the tax point of view assets are depreciated pursuant the Act No. 595/2003 Coll. on Income Tax as amended (hereinafter "Income Tax Act"). Tax depreciations are costs influencing the tax base for corporate income tax purposes.

Strouhal et al. (2013) understand depreciation as estimated amount (expressed at cost), which should the most accurately expressed valued allocation of revenues, which depreciated asset brings to the company – it is resulted that prime focus is not to be calculation of material and external depreciation of assets. By calculation of depreciation charges mean correction of valuated assets in connection with its usage, as the balance sheet precisely expressed financial situation of the company.

If an accounting entity finds out that accounting principles and methods used in the accounting period are not compatible with the requirement of true and fair view, it is obliged to prepare financial statements providing true and fair view of facts, emphasizes Farkaš (2006).

Pakšiová (2014) states that the correct amount of depreciation shall enable a subsequent reproduction of assets after useful life termination what shall secure production ability to the future. Thus she understands as well the preservation of assets nature in company; even she does not use such a word expression.

Depreciation charges represent allocation of initiated acquired expense to the period when the asset should according to the expectation bring benefit. Dvořáková (2012) states that the accounting unit is obliged to prepare depreciation plan which belongs to the internal rules of the company and states ruling for depreciation of tangible assets. The expected period of life of assets should be determined for the particular group of assets that can be related either to the time (time depreciation), or to the performance (performance plan).

By the end of 19<sup>th</sup> and subsequent 20<sup>th</sup> century various methods of depreciation of fixed assets (straight-line, arithmetical or geometric series of progressive, regressive, production methods) have been created and have been stabilized. Accounting forms, accounting of transition items provides accounting transactions to be correctly accrued and to calculate accounting result more precisely (Pakšiová, 2012).

From the accounting point of view no depreciation method of assets is set. Determination of depreciation period is exclusively set on the entity's decision. The shortest period shall not be the most advantageous. It is essential to select depreciation method which should be based on the business plan of an entrepreneur. An entrepreneur should be able to state his case before tax administrator. According to Koleček (2015) it is necessary to consider using alternative solution for including certain types of costs when determining acquisition costs.

Stárová et al. (2014) pointed out that fixed assets are used over a long period of time, and therefore their value is presented in more annual financial statements. Determining the value of tangible fixed assets at the end of every reporting period is thus an important part of book closing in every company. The decision to adjust the value of assets as at the reporting date affects the balance sheet total and also the amount of profit or loss. As at each reporting date, a depreciation plan drawn up for depreciable assets beforehand is to be revised so that an adequate amount of depreciation could be entered into the accounts. In addition, any impairment of assets shall be assessed (beyond regular depreciation).

The aim of accounting depreciation charges is real valuation of tangible assets and provision of major information on costs of accounting unit. Accounting depreciation charges are determined based on the decision of accounting unit. The accounting depreciation charges should be regulated by internal rules of the company. Šteker and Otrusínová (2013) state that tax depreciation charges are determined in accordance with the Income Tax Act and are used only for preparation of corporate income tax return.

Vančurová and Láčková (2014) pointed out that the income tax base can accept the accounting depreciation charges however is up to the taxpayer that accounting depreciation charges represent all aspects of true accounting result. Such practice is for the taxpayer difficult and moreover it does not create same conditions for all taxpayers. The second margin solution is to comply of expenses on acquisition of such assets in the tax base for corporate purposes, so total disconnection by accounting result. Even if exist different method, the most often solution is to specify more or less strict and unified rules for tax depreciation and subsequent correction of accounting result by the difference between accounting and tax depreciation charges.

## 2 METHODOLOGY

The legal arrangements of accounting in the Slovak Republic (hereinafter “SR”) enact accounting records to secure a content of selected provisions of the Income Tax Act in the content and subject of accounting with the interest in costs influencing corporate income tax base of entrepreneurs. The aim of the paper is to present, according to the current law in the SR, a theoretical view on the accounting and tax depreciation of fixed assets before the amendment of tax legislation till 31 December 2014 and after the amendment since 1 January 2015 is presented. The comparison of accounting and tax depreciation calculation and their influence on accounting result and tax base for corporate income tax purposes is assessed on a particular type of fixed assets.

Standard methods of scientific work as the method of selection, analysis and the comparison of selected provisions of the Act No. 431/2002 Coll. on Accounting as amended including related law and the Income Tax Act effective in SR focusing on tax deductible and non-deductible costs influencing corporate income tax base have been used in the topic processing. The mentioned methods present a basic methodical manner of article processing.

Depreciation calculation is compiled in accordance with the following formulas deriving from effective accounting and tax legislation in SR:

Time method of accounting depreciation:

$$\text{Annual depreciation} = \frac{\text{acquisition costs}}{\text{depreciation period}} \quad (1)$$

Straight line method of tax depreciation:

$$\text{Annual depreciation} = \frac{\text{acquisition costs}}{\text{depreciation period}} \quad (2)$$

Accelerated method of tax depreciation:

$$\text{Annual depreciation in the 1st year} = \frac{\text{acquisition costs}}{\text{coefficient for accelerated depreciation in the first year}} \quad (3)$$

$$\text{Annual depreciation in the next years} = \frac{2 \times \text{net book value}}{k - n} \quad (4)$$

where:

*k* – the coefficient for accelerated depreciation in the next years of depreciation

*n* – the number of years for which the assets has been depreciated

## 3 RESULTS AND DISCUSSION

### 3.1 Determination of fixed assets depreciation pursuant accounting and tax aspect

Pursuant legal regulations it is mandatory for all entrepreneurs keeping current accounting and subsequently in the disclosure of financial statements to provide true and fair view on facts which are the subject of accounting. Information on costs, revenues and achieved accounting profit or loss provides the view on income situation of entrepreneurs. Business activity is conditioned by the required amount and structure of assets where evidentially fixed assets are dominated.

Substantial part of fixed assets is created by property, plant and equipment which is in accordance with the Income Tax Act specified by:

- individual technical and economic determination,
- prescribed acquisition costs higher than 1 700 EUR,
- useful life longer than one year.

According to the production classification, property, plant and equipment are considered as machines and devices, vehicles, furniture.

Depreciation of fixed assets belongs to the major subjects of accounting for entrepreneurs. Depreciation of fixed assets shall be applied to the extent and under the conditions prescribed by accounting and tax legal arrangements in the SR. An entrepreneur often incorrectly identifies accounting and tax depreciation costs (charges) and therefore conditions of assets usage are not taken into account. Accounting and tax depreciations charges derive from the measurement of assets in accounting.

An entrepreneur is allowed to decide in an internal directive for accounting whether property, plant and equipment with acquisition costs lower or equal to the amount set in the Income Tax Act will be considered as fixed assets. In case the assets are not included in fixed assets, therefore are not used longer than one year, they are recorded as inventories.

The amendments of the Income Tax Act since 1 January 2015 related to the depreciation of fixed assets constitute the increasing number of depreciation groups from original four depreciation groups to six depreciation groups. The amendment deals with the creation of the third depreciation group with the depreciation period 8 years, mainly consisting of production technologies according to the production classification. Before above mentioned amendment shall support investments to this asset item for the purpose of renewal and modernization of production processes. The newly created depreciation group is the sixth with the depreciation period 40 years, consisting of buildings and constructions of non-production character, flats, hotels, accommodation, administration, cultural, educational facilities and others in accordance with the production classification. The amendment is to be realized for the purpose of making the useful life of this asset item more realistic.

Straight line method of depreciation might be applied for fixed assets for tax purposes, except for assets included in the second and third depreciation groups, where an entrepreneur is allowed to select accelerated depreciation method, depending on the advantageous influence of depreciation on the corporate income tax base. The amendment is focused on making selected types of fixed assets of technological character advantageous in comparison with other non-production technologies. The amendments shall be applied for already depreciated assets.

From accounting and as well tax point of view in the first year of asset depreciation it is allowed to apply only proportion of annual depreciation depending on the number of months from putting into use till the end of taxable period. In the next years of depreciation the calculated annual depreciation is applied fully.

### **3.2 Depreciation of fixed assets pursuant the accounting legislation**

Fixed assets are depreciated indirectly by means of accounting depreciation. Currently effective legal arrangements in SR allow facultative approach to depreciation methods from the accounting point of view. The plans of accounting depreciation are compiled when fixed assets are put into use. During the useful life of depreciated assets the accounting depreciation presents the real wear and tear which is brought to the value of outputs by means of costs from economic activity. Depreciation costs cause a decrease in accounting profit or loss.

Depreciation plan presents an accounting record related to real physical and moral wear and tear of particular asset, intensity of usage and total useful life. According to changing conditions depreciation plan is reassessed and pursuant accounting regulations the selected method of depreciation might be changed in one accounting period but in the immediately subsequent period if it requires fair presentation of the accounting subject. The meaning of that is based on the obligation to express real wear and tear of assets corresponding to the normal conditions of use. Depreciation plan as an accounting record shall be archived for five years following the year to which it relates.

The calculation procedure of accounting depreciation of fixed assets is based on the example when an entrepreneur acquired and put into use a truck at acquisition costs of EUR 29 900 in July 2013. Table 1 documents the calculation of accounting depreciation of the truck using the time method of depreciation with expected useful life of the asset four years.

Tab. 1 – Plan of accounting depreciation charges (in EUR). Source: own calculations

Depreciation period in years	Accounting depreciation	Accumulated depreciation	Tax net book value
2013	3 738	3 738	26 162
2014	7 475	11 213	18 687
2015	7 475	18 688	11 212
2016	7 475	26 163	3 737
2017	3 737	29 900	0

Net book value is determined as a difference of acquisition costs of a truck and accumulated depreciation of a fixed asset. The asset is depreciated till its amount of measurement in accounting.

### **3.3 Tax depreciation of fixed assets before the amendment of the Income Tax Act till 31 December 2014**

From the tax point of view depreciation presents maximal possible burden of an entrepreneur regardless real wear and tear of an asset. Pursuant the Income Tax Act and for the purposes of calculation of corporate income tax base, tax depreciation of fixed assets is performed while tax depreciation is allowed to be applied in tax charges only if a depreciated asset is used for securing of taxable income and an entrepreneur records an asset in his accounting books. Tax depreciation presents allowed impact on corporate income tax base and is not recorded in accounting books.

The classification of a particular type of fixed assets to suitable depreciation group is performed in accordance with Appendix No. 1 of the Income Tax Act. The set of movable assets is classified to depreciation group according to its main functional unit which must be determined by an entrepreneur. Fixed assets which cannot be classified to depreciation groups according to the mentioned appendix are generally classified to the second depreciation group. Fixed assets are depreciated by the straight line or accelerated method of tax depreciation. Tax depreciation method shall not be changed during the whole depreciation period, i. e. since putting into use till its disposal.

Table 2 determines the calculation procedure of tax depreciation of a truck acquired and put into use at acquisition costs 29 900 EUR in July 2013 using the accelerated method of depreciation pursuant the Income Tax Act effective till 31 December 2014. According to the production classification a truck is classified to the first depreciation group with the depreciation period 4 years.

Coefficients are assigned to depreciation groups for accelerated method of fixed assets depreciation prescribed by the Income Tax Act. In the first year of fixed assets depreciation only proportion of annual depreciation is applied depending on the number of months from putting into use till the end of a taxable period. In the second year of depreciation net book value for calculation purposes is determined as a difference between acquisition costs of assets and calculated annual tax depreciation in the first year of depreciation unshortened to unclaimed proportion of depreciation. In the next year net book value is set as a difference of net book value determined in the first year of depreciation and calculated depreciations beginning the second year of depreciation. Depreciation period is prolonged because the proportion of unclaimed calculated annual depreciation in the first year is applied until the year following the expiration of the depreciation period.

Tab. 2 – Plan of accelerated tax depreciation charges (in EUR). Source: own calculations

Depreciation period in years	Tax depreciation	Accumulated depreciation	Tax net book value
2013	3 738	3 738	22 424
2014	11 212	14 950	11 212
2015	7 475	22 425	3 737
2016	3 737	26 162	0
2017	3 738	29 900	x

Deriving from the example of truck depreciation from the accounting and tax point of view there arise differences which are determined in Table 3. Pursuant the Income Tax Act depreciations are tax deductible expenses (costs) for achieving, securing and maintaining of income (revenues) from business with the influence on income tax base. Accounting costs from depreciation of a truck are recognized in the amount of tax depreciation in year 2013 and 2015. This means that the tax base is affected only by the differences between the accounting and tax depreciation charges of fixed assets.

Tab. 3 – Differences between accounting and tax depreciation charges (in EUR).

Source: own calculations

Depreciation period in years	Accounting depreciation	Tax depreciation	Accounting depreciation – tax depreciation
2013	3 738	3 738	0
2014	7 475	11 212	- 3 737
2015	7 475	7 475	0
2016	7 475	3 737	+ 3 738
2017	3 737	3 738	- 1

In double entry accounting of entrepreneurs accounting depreciation influence profit or loss by means of costs (Table 4). Costs in the form of accounting depreciation from unused assets not participating in the creation of revenues from economic activity, negatively impact on real calculation of an accounting result. Legal regulations of entrepreneur's accounting in SR prescribe the determination manner of accounting profit or loss before corporate income tax which presents a base for income tax base determination.

Transformation of accounting profit or loss to income tax base is effected by difference between accounting and tax depreciation charges. Difference between higher accounting depreciation than tax depreciation charges in year 2016 (Table 4) which is not considered as tax deductible, is added to profit or loss before taxes. On the other side a difference between lower accounting depreciation than tax depreciation charges in year 2014 and 2017 is

deducted. The following cost adjustments are performed in order to calculate correctly income tax base and subsequently to calculate income tax which reduces profit or loss before taxes. In year 2013 for the calculation of corporate income tax the tax rate was used in the amount 23 %. In years 2014 and 2015 the tax rate of corporate income tax was decreased to 22 % due to the introduction of tax licences. In the following years 2016 and 2017 the currently valid corporate income tax rate of corporate income tax is presupposed to remain the same when calculating a tax liability.

Tab. 4 – Transformation of accounting result into corporate income tax base (in EUR).

Source: own calculations

Year	Revenues	Costs (accounting depreciation)	Profit before taxes	Accounting depreciation – tax depreciation	Income tax base	Income tax	Net income
2013	192 000	3 738	188 262	0	188 262	43 300,26	144 961,74
2014	192 000	7 475	184 525	- 3 737	180 788	39 773,36	144 751,64
2015	192 000	7 475	184 525	0	184 525	40 595,50	143 929,50
2016	192 000	7 475	184 525	+ 3 738	188 263	41 417,86	143 107,14
2017	192 000	3 737	188 263	- 1	188 262	41 417,64	146 845,36

Legal arrangements of entity's accounting in SR prescribe that accounting records shall secure also the content of effective tax legislation. It presents an obligation which shall take into account the classification pursuant requirements for tax base calculation when creating analytical accounts to synthetic accounts. For costs which are deductible only in law prescribed amount, it is evitable to create analytical accounts to the appropriate synthetic accounts. In the process of their creation it is essential to take into account accounting and tax point of view, i. e. tax deductibility or tax non-deductibility.

### **3.4 Tax depreciation of fixed assets after the amendment of the Income Tax Act since 1 January 2015**

For the comparison Table 5 documents the calculation of tax depreciation of a truck pursuant the Act No. 333/2014 Coll. which amended the Income Tax Act effective since 1 January 2015. An entrepreneur commenced depreciating a mentioned asset type after its putting into use in year 2013 by accelerated method of depreciation. As regards the amendment of legal regulation of fixed assets tax depreciation, the asset classified to the first depreciation group might be depreciated only by the straight line method in years 2015 and 2016. According to transitional provisions of the Income Tax Act the applied tax depreciation of a truck are not adjusted retrospectively in years 2013 and 2014.

When the straight line method of depreciation is applied, in years 2015 and 2016 the annual depreciation is determined as a ratio of acquisition costs of fixed assets and depreciation period appropriate for a particular depreciation group pursuant the Income Tax Act. Net book value is determined as a difference of acquisition costs and accumulated depreciation. Annual depreciations attributable to the depreciation period are calculated up to the amount of assets acquisition costs.

Tab. 5 – Plan of tax depreciation charges (in EUR). Source: own calculations

Depreciation period in years	Tax depreciation	Accumulated depreciation	Tax net book value
2013	3 738	3 738	22 424
2014	11 212	14 950	11 212
2015	7 475	22 425	7 475
2016	7 475	29 900	0

Accounting depreciation influence accounting result determined in the accounting books. Tax base for income tax purposes is affected by tax depreciation charges and therefore by incurred differences between accounting and tax depreciation charges from fixed assets. In year 2014 a difference between applied lower accounting depreciation and higher tax depreciation charges (Table 6) presents an item reducing tax base. On the other side a tax non-deductible item to profit or loss before taxes is only accounting depreciation of a truck in year 2017.

Tab. 6 – Differences between accounting and tax depreciation charges (in EUR).

Source: own calculations

Depreciation period in years	Accounting depreciation	Tax depreciation	Accounting depreciation – tax depreciation
2013	3 738	3 738	0
2014	7 475	11 212	- 3 737
2015	7 475	7 475	0
2016	7 475	7 475	0
2017	3 737	x	+ 3 737

Accounting profit or loss before taxes is adjusted to income tax base by means of deductible and non-deductible items. Difference between accounting and tax depreciation charges which in year 2017 presents non-deductible item to income tax base, reduces net income (Table 7) and vice versa.

Tab. 7 – Transformations of profit or loss to corporate income tax base (in EUR).

Source: own calculations

Year	Revenues	Costs (accounting depreciation)	Profit before taxes	Accounting depreciation – tax depreciation	Income tax base	Income tax	Net income
2013	192 000	3 738	188 262	0	188 262	43 300,26	144 961,74
2014	192 000	7 475	184 525	- 3 737	180 788	39 773,36	144 751,64
2015	192 000	7 475	184 525	0	184 525	40 595,50	143 929,50
2016	192 000	7 475	184 525	0	184 525	40 595,50	143 929,50
2017	192 000	3 737	188 263	+ 3 737	192 000	42 240,00	146 023,00

At the microeconomic level, the optimization of the tax burden means achieving a minimum amount of tax liabilities of entrepreneurs. In order to assess this problem there are no indicators in contrast to the macroeconomic level. Tax optimization relates mainly to corporate income tax and is usually solved by the analysis of the accounting profit or loss transformation to the corporate income tax base. For entrepreneurs it presents an alternative to increase their net income and thus their own financial resources needed for investment.

## 4 CONCLUSION

Entrepreneurs demonstrate all facts for tax purposes by means of accounting records. The subject and content of accounting influence taxation of entrepreneur's income since it presents the data for determination of tax base for corporate income tax purposes and subsequently corporate income tax liability.

Last amendments in fixed assets tax depreciation deal with the classification of assets to depreciation groups and its associated changes in depreciation periods. The possibility of accelerated depreciation method has been restricted to selected depreciation groups.

Pursuant the Income Tax Act tax depreciation of fixed assets calculated by the mentioned Act presents tax charges (expenses). On the other side accounting depreciation should reflect the real status of assets. Therefore, the differences between accounting and tax depreciation charges occur increase or decrease an accounting profit or loss in the process of transformation to corporate income tax base. These adjustments are performed out of accounting books.

By means of tax deductible costs (expenses) in the form of fixed assets tax depreciation it is possible to decrease corporate income tax base and as well annual corporate income tax liability. When the straight line method of depreciation is applied, depreciations present tax deductible costs in the same amount during individual years of depreciation, except for the year when an asset was put in use. When the accelerated depreciation method is applied, tax deductible costs of depreciation are higher at the beginning of depreciation while in the next years their amount is gradually decreasing. When in the first years there are higher tax depreciations than accounting depreciations, it is possible to decrease income tax base and subsequently corporate income tax in a bigger extent. By the correct application of fixed assets depreciation methods, it is feasible to partially optimize the tax base. After the amendment of tax legal regulation of assets depreciation the before mentioned statement is possible only in case when assets are classified in the second or third depreciation group. The entrepreneur's decision on assets depreciation method should be influenced by the development of profit or loss in the consequent years. As regards the amendments of legal regulations of fixed assets tax depreciation in SR, namely restricted possibility of accelerated depreciation, in our view that the tax depreciation ceases to be a tool for optimizing the tax base for corporate income tax purposes.

Accounting records secure the verifiability of the Income Tax Act provisions in the subject and content of accounting and as well by creating of analytical accounts to synthetic accounts according to selected criteria. Requirements for analytical evidence deal with the providing of accounting data to all management levels as well as external users.

## **SOVEREIGN WEALTH FUNDS: WEALTH, ASSETS AND RESERVES**

*Antonia Ficova, Juraj Sipko*

### **Abstract**

The paper explores impact on businesses and GDP of countries that set up SWFs. First, we found that 99.86 percent of the changes of businesses are being explained by variables of Gross Operating Expense in the country, Shareholders' equity, SWF assets, Balance Sheet-income: total assets, Total reserves (includes gold, current US). Second, we explore impact of Volume of imports of goods and services, Volume of exports of goods and services, SWF assets and GDP growth rate on GDP of 44 countries with SWFs, we found that model is significant at 84.49%. Third, we focus on reserves of 18 observed countries with SWFs, we determined the reliability of proportion of total reserves. Findings indicate positive relationship.

## **1 INTRODUCTION**

However, controls to the free movement of goods and capitals have been greatly reduced in many economies, some of them still place restrictions on foreign equity investment and capital flows. In other words, some country that set up Sovereign Wealth Funds (SWF's) to sort of tariff barriers to international trade to protect domestic strategic industries.

Nevertheless, strong growth in outward foreign direct investment (OFDI) from developing countries has become important key of the twenty-first century. This OFDI flows come from state-owned enterprises, SWF's as well as private enterprises operating as multinational companies from a home base or as free-standing companies.

Ad rem, interesting is that Government Pension Fund Global according to NBIM bought a 50 percent stake in seven properties in and around Paris from AXA Group in July 2011. More to the point, Norway's fund's largest equity holdings include: Royal Dutch Shell Plc, Nestlé SA, HSBC Holdings Plc, Novartis AG, Vodafone Group Plc, Apple Inc, Exxon Mobil Corp, Roche Holding AG, BP PLC, GlaxoSmithKline Plc. On the other hand, Abu Dhabi has multiple SWFs with different focuses, exempli gratia 9% stake of Apollo Management, 20% of Ares Management Citigroup and 15% of Gatwick Airport. In short, SWFs have appeared in public since 2007 due to their heavy investments in Western corporations, what have been mentioned supra. Viewed in this light, SWFs show absolutely a remarkable size mainly through these investments have become systemically relevant.

Ergo the question is: How can the size of companies influence the economic growth of a country that set up SWF? In other words, in developed as well as developing countries, we can find different types of industrial companies that the size, number and collaboration of companies can hardly influence the industrial development of the whole country. What is best for a country to have, a small number of huge companies that earn billions or a large number of small to medium companies that interact with each other? Essentially, some countries have pursued the strategy of subsidizing national champion firms to compete in the world economy, that seems to work so long as basic market discipline is enforced in terms of

investment decisions. Moreover, direct SWF Investments include: Mubadala Development Company; U.A.E. made USD 7,000.00 deal in Aluminium in the Sarawak (SCORE) Malaysia. Qatar Investment Authority made USD 2,800.00 deal in Agricultural Bank of China. International Petroleum Investment Company; U.A.E. bought 4.99% stake of UniCredit Spa in Italy. Qatar Investment Authority bought 100% of Harrods in U.K.

It is important to mention following positive facilitators of economic growth of its home territory: First, its innovativeness, that means the creation of intellectual assets (patents, trade secrets, copyrights, licences that can enable the firm to harvest revenues from the rest of the world). Second, tied very closely to the first factor would be its talent management systems. Third, its competitiveness (driven by leadership, innovation, productivity, efficiencies). Fourth, its global footprint or reach: including its networks and last one is its quality standards.

A significant factor which determine growth of SWF's is amount of foreign exchange reserves. Nonetheless, real effective exchange rates in surplus economies like China, Korea, continue to build up their foreign reserves. In this case, when these economies has a stronger exchange rate, combined with structural reforms would raise domestic purchasing power and contain inflation pressure. So the fact is that if prices of commodities will be rise, governments in commodity-exporting countries will be continue accruing foreign assets. For example Singapore's Government Investment Corporation was set up in 1981 to manage the country's foreign exchange reserves. However, in 2013, the 15 participating companies, who are all members of the World Gold Council, spent US 22.5bn in payments to businesses in the countries where their mines are producing gold and a further US 3.8bn in payments to businesses in countries where their projects are yet to produce gold.

Monk (2010) presents that the jolt prompting the creation of SWFs was the 1997 Asian financial crisis. This crises led to changes in the demand for international reserves, increasing the accumulating by affected countries. For example, Singapore, which had considerable pre-existing reserves, escaped the Asian crisis relatively unscathed. The accumulation of reserves has been a strategy of crisis prevention. The value of accumulated reserves quickly grew to exceed the level needed by countries for insurance purposes, extremely costly. In short, cost of reserves in emerging market countries are around 1% of GDP annually. By accumulating reserves we should look at issues such as exchange rate appreciation, liquidity expansion, financial sector imbalances, inflation. It may also include opportunity costs. On the other hand, when countries transfer excess reserves to SWF's, that may help isolate the economy from negative effects of reserve accumulation, like reducing costs of sterilisation by issuing domestic debt to avoid inflation.

There are many SWFs with multiple objectives, based on Al-Hassan, A. et al. (IMF, 2013) and the Santiago Principles taxonomy, five types of SWFs can be distinguished as follows: First, *stabilization funds* are set up to insulate the budget and economy from commodity price volatility and external shocks (e.g., Chile (Economic and Social Stabilization Fund), Timor-Leste, Iran, and Russia (Oil Stabilization Fund)). They tend to invest largely in highly liquid portfolio of assets by allocating over 80 percent of their assets to fixed income securities, with government securities consisting around 70 percent of total assets. Second, *savings funds* intend to share wealth across generations by transforming nonrenewable assets into diversified financial assets (Abu Dhabi Investment Authority, Libya, Russia (National Wealth Fund)). Their investment mandate emphasizes high risk-return profile, thus, allocating high portfolio shares to equities and other investments (over 70 percent). Third, *development funds* are established to allocate resources to priority socio-economic projects, usually infrastructure (e.g., UAE (Mubadala) and Iran (National Development Fund)). Fourth, *Pension reserve funds* are set up to meet identified outflows in the future with respect to pension-related

contingent-type liabilities on the government's balance sheet (e.g., Australia, Ireland, and New Zealand). They held high shares in equities and other investments to offset rising pension costs. Fifth, *Reserve investment corporations* intend to reduce the negative carry costs of holding reserves or to earn higher return on ample reserves, while the assets in the funds are still counted as reserves (e.g., China, South Korea, and Singapore). To achieve this objective, they pursue higher returns by high allocations in equities and alternative investments, with up to 50 percent in South Korea and 75 percent in Singapore's Government Investment Corporation.

The question is: How transparent are investments of SWF's? Viewed in this light, is necessary to mention Carl Linaburg and Mich Maduell developed The Linaburg-Maduell Transparency Index, includes ten essential principles. That is a method of rating transparency in respect to SWFs through principles. In other words, mainly intended for government-owned investment vehicles, where were fears from unethical agendas. According to the SWF Institute 3Q 2014 LMTI, by using this method highest score gained Chile, UAE-Mubadala, Singapore-Temasek, Ireland NPRF, Azerbaijan, Australian Future Fund, Alaska, Norway GPFG Fund, New Zealand, Canada. Conversely lower score gained funds like Algeria, Brunei, Kiribati, Mauritania, Venezuela. These transparency ratings may change, depend from additional information funds.

### **1.1 The objectives**

The research objectives of this paper are presented as follows: First, how may expense, shareholders equity, SWF assets, total assets of the country, total reserves of the country influence on businesses in the countries that set up SWF? In other words, larger companies can exploit cost advantages in all aspects of businesses by producing more. They are in a position to use new capital intensive technology at a lower average cost and so they expand businesses further. Second, how openness, more to the point volume of exports and imports, assets of SWFs, GDP growth rate may affect GDP of country with SWF? In other words, most SWFs are driven by export of oil, minerals. Third, what is amount of gold reserves of countries with SWFs? In sum, the accumulation of official external assets, several of which are SWF's, tends to underestimate the importance of capital inflows as a source of reserve accumulation.

### **1.2 Data and methodology**

This paper provides following econometric models. First, we observe 18 countries that set up SWF's and we examine impact of Gross operating expense in the country (US Million), Shareholders' equity, SWF assets (US billion), Balance Sheet-income: total assets (US Million), Total reserves (includes gold, current US) on businesses. Second, we examine impact of Volume of imports of goods and services (Percent change), Volume of exports of goods and services (Percent change), SWF assets (US billion) and GDP growth rate (annual %) on GDP of 44 countries with SWFs. Third, we focus on reserves of 18 observed countries with SWFs, we determined the reliability of proportion of total reserves of observed countries. This has been done by illustrations and calculations by author by using economic software Eviews, moreover by using available data from OECD database of 2013, World Bank Database of 2013, International Monetary Fund, World Economic Outlook Database, October 2014 and Sovereign Wealth Fund Institute 2015. In addition to this, we present the estimations by using Ordinary Least Squares (OLS), correlation matrix, The 'Student' t-test distribution with (N-1) degrees of freedom, Scatter graphs.

### **1.3 Structure of the study**

Outline of the paper is composed as follows: Section 2 presents briefly literature, findings of authors on this subject. Ergo, the main contribution of this paper is contained in section 3 that

provides econometric models, moreover examined hypotheses of observed countries, etc. Section 4 concludes the paper.

## **2 LITERATURE REVIEW**

There are many different definitions of a SWF's. On the one hand, the EU Commission (2008) describes SWF's as state owned investment vehicles, which manage a diversified portfolio of domestic and international financial assets. Id est, SWF's are mainly created when countries have surplus revenues, reserves and their governments feel it would be advantageous to manage these assets with a view to future liquidity requirements and as a way of stabilising irregular revenue streams argued by Gugler, P.; Chaisse, J. (2009). Miracky and Bortolotti (2009) presented definitions of SWFs as follows: (i) an investment fund rather than an operating company, (ii) that is wholly owned by a sovereign government, in other words organized separately from the central bank or finance ministry to protect it from excessive political influence, (iii) that makes international and domestic investments in a variety of risky assets, (iv) that is charged with seeking a commercial return, and (v) a pension fund, the fund is not financed with contributions from pensioners and does not have a stream of liabilities committed to individual citizens.

Non obstante, it is important to mention a number of studies on the subject of SWFs since 2007. In this section we present related research of academics. Jones, S. G. - Ocampo, J. A., (2008) presented in details the evolution of foreign exchange assets in different parts of the developing world, optimal reserves, developed a broader framework for the analysis of the motives for the accumulation of foreign exchange assets. Matoo, A. - Subramanian, A. (2008) described imbalances between undervalued exchange rates and SWFs. They proposed new rules in the WTO to discipline cases of significant undervaluation that are clearly attributable to government action. Beck, R.; Fidora, M. (2008) provided background of the impact of sovereign wealth funds (SWFs) on global financial markets, impact of a transfer of traditional foreign exchange reserves to SWFs on global capital flows. Among authors examined subject of SWF, Baptista, A. M. (2008), Miracky et. al. (2009), Bernstein, S.; Lerner, J.; A. Schoar (2009). Al-Hassan, A. *et al.* (IMF, 2013) presented a systematic (normative) manner the salient features of a SWF's governance structure, in relation to its objectives and investment management that can ensure its efficient operation and enhance its financial performance. Bortolotti et. al. (2013) examined of 1.018 Sovereign Wealth Fund (SWF) equity investments in publicly traded firms and a control sample of 5.975 transactions by private-sector financial institutions over 1980-2012. Bodie, Z., Brière, M., (2013) described management of sovereign wealth from the perspective of the theory of contingent claims. They suggest institutional arrangements that could overcome this obstacle and enable efficient coordination. Chen, S. Y. (2013) addressed certain issues that may arise where a SWF is a claimant in investor-state arbitration. In short, SWFs should not be discouraged from settling issues with a host state through investor-state arbitration. Rose, P. (2014) described the evolution of foreign investment regulation in recent years, analysis of Foreign Investment in the United States Act (FINSAs), including the key statutory definitions that determine the regulatory pathway of a foreign investment transaction. Gelb *et. al.* (The World Bank, 2014) focused on the main priorities concern the criteria for selecting investments, partnerships, external and internal governance arrangements, transparency, reporting and consistency with macroeconomic policy. Backer, L. C. (2014) described that SWFs incarnate and replicate the collisions between two tectonic forces that are grinding their way to a new normative framework of governance and power. Etemad, A. (2014) has explored the effect of the sovereign funds on the volatility of macro-variables. The author showed that countries with oil funds have decreased the volatility of consumer prices and broad money compared to countries without

funds. Gilligan *et al.* (2014) noted that there are inescapable political dimensions to SWFs and other forms of state capital.

Ciarlone, A.–Miceli, V. (2014) investigated the determinants of the investment activity of SWF's at a macro level, with special emphasis on the possible reaction to a financial crisis in a potential target economy, especially 1,903 acquisition deals spanning the period 1995-2010 and involving 29 out of the 69 existing SWFs. Naveen, T. (2014) examined further investment in infrastructure and by explaining why SWFs could help. Van Den Bremer, Ton - van der Ploeg, Rick - Wills, S. (2014) found that commodity exporters should change the allocation of their SWF by leveraging all risky assets and hedging subsoil oil risk. On the other hand, consumption should be a constant share of total oil and fund wealth. Third, if oil wealth cannot be adequately hedged. Ghahramani, S. (2014) presented three models of sovereign-driven portfolio investment (in contrast to foreign investment) and how governments may pursue international law principles through shareholder activism.

### 3 HYPOTHESES

Based on data analyzed for the paper, we developed et sequentes hypotheses. Results are demonstrated in this section.

#### 3.1 Testing Hypothesis I.

In this section, we want to examine the dependence, moreover how changes in following factors x: Gross operating expense in the country (US Million), Shareholders' equity, SWF assets (US billion), Balance Sheet, income: total assets (US Million), Total reserves (includes gold, current US) may affected businesses in the countries that set up SWF. Variable of business (US mln) provides information on number of companies and employees, gross premiums, within the sector in the country that set up SWF. In sum, the number of domestic undertakings, foreign controlled undertakings, branches and agencies of foreign undertakings. In other words, we use data of 18 countries that set up SWF, available data from OECD database of 2013, World Bank Database of 2013 and Sovereign Wealth Fund Institute 2015. In this context, Sovereign Wealth Fund presents 77 SWF's in 58 countries around the world, with total assets US 7.071.2 tn in January of 2015. The question is: How conditions of the country that set up SWF, that are mentioned above may affect businesses. We observed following countries: Australia, Brazil, Canada, France, Hong Kong, China, Chile, Indonesia, Ireland, Italy, Korea, Malaysia, Mexico, New Zealand, Norway, Panama, Peru, Singapore, United States.

Note:

\* China SWF includes: China Investment Corporation, SAFE Investment Company, Hong Kong Monetary Authority Investment Portfolio, National Social Security Fund, China-Africa Development fund.

\* US SWF includes: Alaska, Texas, New Mexico, Wyoming, Alabama, Louisiana.

We use method of least squares by using economic software Eviews, N=18 at 95 percent of probability,  $\alpha=0,05$ ; see bellow.

Tab. 1 – Ordinary Least Squares (OLS) of Businesses. Source: Author's estimation by using Eviews.

Dependent Variable: BUSINESSES				
Method: Least Squares				
Sample: 1 18				
Included observations: 18				
Variable	Coefficient	Std. Error	t-Statistic	Prob.

GOLD RESERVES	1.23E-08	5.85E-09	2.098	0.057
SHAREHOLDERS EQUITY	1.761	0.290	6.073	0.000
SWF ASSETS	-9.593	11.270	-0.851	0.411
TOTAL ASSETS	0.004	0.030	0.146	0.886
GROSS OPERATING EXPENSES	0.997	0.015	65.250	0.000
C	1112.415	3566.428	0.311	0.760
<hr/>				
R-squared	0.998	Mean dependent var	103794.1	
Adjusted R-squared	0.998	S.D. dependent var	239695.1	
S.E. of regression	10655.84	Akaike info criterion	21.64681	
Sum squared resid	1.36E+09	Schwarz criterion	21.943	
Log likelihood	-188.821	Hannan-Quinn criter.	21.687	
F-statistic	1717.968	Durbin-Watson stat	1.7623	
Prob(F-statistic)	0.000			

Results coming out from OLS show following estimation equation of model:

$$\text{Businesses} = \beta_0 + \beta_1 * \text{gold reserves} + \beta_2 * \text{shareholders equity} - \beta_3 * \text{SWF assets} + \beta_4 * \text{total assets} + \beta_5 * \text{gross operating expenses}$$

And after substituted coefficients we get formula as follows:

$$\text{Businesses} = 1112.414 + \beta_1 * 1.22852539081e-08 + \beta_2 * 1.761 - \beta_3 * 9.593 + \beta_4 * 0.004 + \beta_5 * 0.997$$

According to the results of OLS at 95% confidence level, which are presented in Table 1 above show, that coefficient of determination  $R^2 = 0.998$  indicates that 99.86% of the variance of the endogenous variable (businesses) is being explained by changes in the variables x, that shows gold reserves, shareholders equity, SWF assets, total assets, in short that means positive linear relationship. On the other hand, 0.14% of changes in the businesses in the countries that set up SWF may be affected by other variables that are not included in this model, for example rate of economic growth of the country, inflation, government restrictions (higher tax rate, exchange rate, interest rate), etc. In sum, businesses in the countries that set up SWFs are more affected to total reserves of the country, it may depend on the area of the country), shareholders equities (owned by foreign or national), gross operating expenses in the firms in positive relationship.

Ipsa facto, the significance of the model, prob (F-statistic) is  $0.000000 < 0.01$ ; what is high statistically significant (++). The parameter  $\beta_2$ ,  $\beta_5$  are high statistically significant because of the P-value is  $0.0000 < 0.01$ ; (++). The parameter of gold reserves are statistically significant because of the P-value is  $0.057 < 0.05$ . For  $N = 18$ ,  $k = 5$ , and significant level = 5%, the significant Durbin-Watson statistic dL is 0.522, dU is 1.803. Since the Durbin-Watson d statistic,  $4 - 1.803 = 2.197$ , a value near 2 indicates non-autocorrelation in this model.

However, at this point we present illustrations of significant variables below. Moreover, the data are displayed as a collection of points, each having the value of one variable determining the position on the horizontal axis and the value of the other variable determining the position on the vertical axis. If the pattern of dots slopes from lower left to upper right, it suggests a positive correlation between the variables being studied, e. g. gross operating expenses to businesses, shareholders equity and total assets to business. If the pattern of dots slopes from upper left to lower right, it suggests a negative correlation, e.g. SWF assets to businesses, see below.

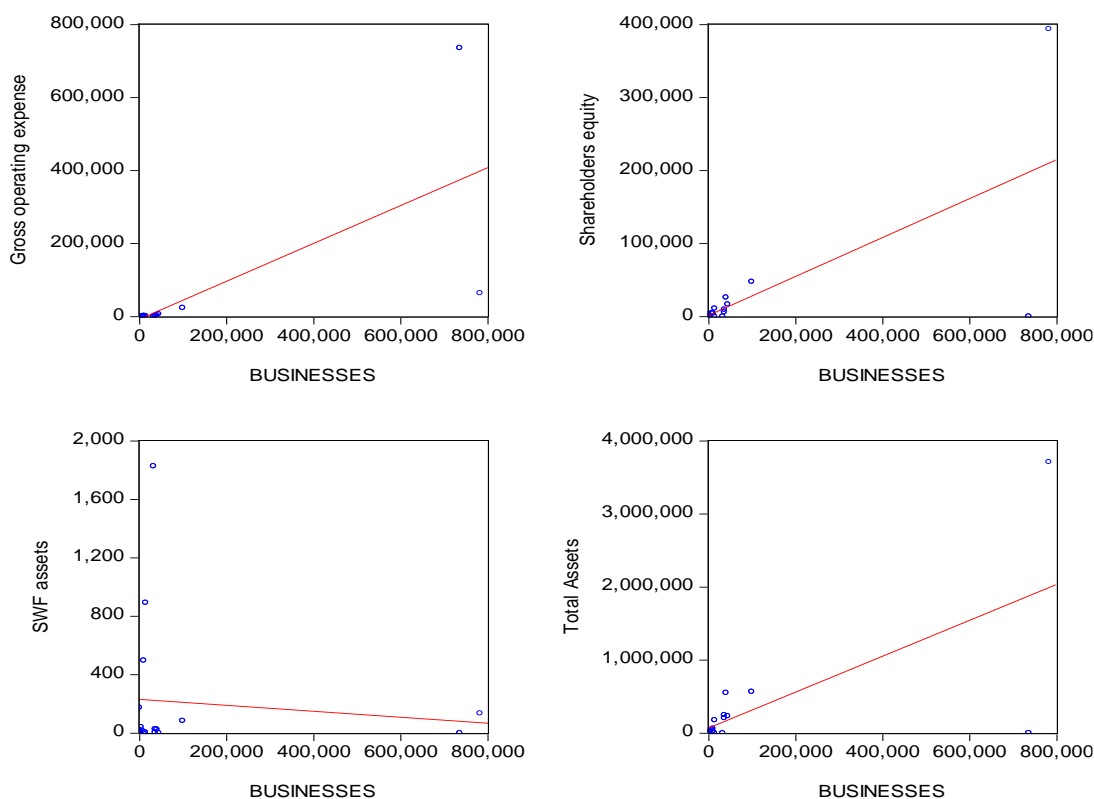

Fig. 1 – Simple Scatter Graphs of significant variables. Source: Author’s estimation by using Eviews.

For more details we provide statistics of observed variables that we used in this model as follows:

Tab. 1 – Summary Statistics. Source: Author’s estimation according to financial data of observed countries that set up SWF by using economic software Eviews.

	SHAREHOLD				TOTAL ASSETS	GROSS OPERATING EXPENSE
	BUSINESSE	GOLD RESERVES	ERS EQUITY	SWF ASSETS

### 3.2 Testing Hypothesis II.

At this point, we examine the dependence, moreover how following factors *exempli gratia*: Volume of imports of goods and services (Percent change), Volume of exports of goods and services (Percent change), SWF assets (US billion) and GDP growth rate (annual %) may contribute to changes of Gross domestic product, constant prices (Percent change) of countries that set up SWF.

Viewed in this light, we focus on 44 countries with SWF as follows: Algeria, Angola, Australia, Azerbaijan, Bahrain, Botswana, Brazil, Brunei Darussalam, Canada, France, Gabon, Ghana, Guinea, Chile, China, Indonesia, Iraq, Islamic Republic of Iran, Ireland, Italy, Kazakhstan, Kuwait, Kiribati, Libya, Malaysia, Mauritania, Mexico, New Zealand, Nigeria, Norway, Oman, Panama, Peru, Qatar, Russia, Saudi Arabia, Singapore, South Korea, Trinidad and Tobago, Turkmenistan, United Arab Emirates, Venezuela, Vietnam, United States. We observed data from International Monetary Fund, World Economic Outlook Database, October 2014, World Bank Database, 2013 and Sovereign Wealth Fund Institute, January 2015.

The question is: How export, import (openness of the country) and assets of SWF may affect GDP of the country that set up SWF. However, some countries that set up SWF still place restrictions on foreign investments. Viewed in this light, these obstacles can negatively affect the decision to invest in a certain country. In this context, we examined factors openness to the international movement of goods and capital: the volume of exports and imports, on the one side, and the SWF value, growth rate, scaled to the country's GDP.

Note:

\* SWF assets; UAE includes: Abu Dhabi Investment Authority, Abu Dhabi Investment council, Investment corporation of Dubai, International Petroleum Investment company, Mubadala Development company, Emirates Investment Authority, RAK Investment Authority.

We use method of least squares by using economic software Eviews, N=44, k=4 at 95 percent of probability,  $\alpha=0,05$ ; see bellow.

Tab. 1 – Ordinary Least Squares (OLS) of GDP. Source: Author's estimation by using Eviews.

Dependent Variable: GROSS DOMESTIC PRODUCT				
Method: Least Squares				
Sample: 1 44				
Included observations: 44				
Variable	Coefficient	Std. Error	t-Statistic	Prob.
VOLUME OF IMPORTS	0.085	0.043	1.936	0.060
VOLUME OF EXPORTS	0.210	0.033	6.366	0.000
SWF ASSETS	4.82E-05	0.000	0.060	0.951
GDP GROWTH RATE	0.533	0.086	6.171	0.000
C	0.830	0.387	2.145	0.038
R-squared	0.844	Mean dependent var		2.956
Adjusted R-squared	0.829	S.D. dependent var		4.313
S.E. of regression	1.783	Akaike info criterion		4.101
Sum squared resid	124.089	Schwarz criterion		4.304
Log likelihood	-85.243	Hannan-Quinn criter.		4.177
F-statistic	53.121	Durbin-Watson stat		2.117
Prob(F-statistic)	0.000			

According to results coming out from OLS show following estimation equation of the model:

$$\text{Gross Domestic Product} = \beta_0 + \beta_1 * \text{volume of imports} + \beta_2 * \text{volume of exports} + \beta_3 * \text{SWF assets} + \beta_4 * \text{GDP growth rate}$$

And after substituted coefficients we get formula as follows:

$$\text{Gross Domestic Product} = 0.830 + \beta_1 * 0.085 + \beta_2 * 0.210 + \beta_3 * 4.82181068712e-05 + \beta_4 * 0.533$$

According to the results of OLS at 95% confidence level, which are presented in Table 1 above show, that coefficient of determination  $R^2 = 0.844$  indicates that 84.49% of the variance of the endogenous variable (gross domestic product) is being explained by changes in the variables x, that includes volume of import, volume of export, SWF assets, GDP growth rate, in short that means positive linear relationship. On the other hand, 15.51% of changes in the GDP of the country that set up SWF may be affected by other variables that are not included in this model, for example rate of current account balance, debt to GDP, etc. In addition to the variables that have been mentioned above, we include several other factors that have the potential of explaining the GDP of the country that set up SWF. However, we have also examined inflation rate and interest rate as well, but these factors are not significant, moreover we did not include these factors in this model.

The significance of the model, prob (F-statistic) is  $0.000 < 0.01$ ; what is high statistically significant (++). Variables examined in this model are significant. The parameter  $\beta_2$ ,  $\beta_4$  are high statistically significant because of the P-value is  $0.000 < 0.01$ ; (++) and  $\beta_1$  is statistically significant as well. Moreover, for  $N = 44$ ,  $k = 4$ , and significant level = 5%, the significant Durbin-Watson statistic dL is 1.156, dU is 1.528. Since the Durbin-Watson d statistic,  $4 - 1.528 = 2.472$ , a value near 2 indicates non-autocorrelation in this model.

At this point we present correlation matrix of model of GDP. Following table show correlation between variables.

Tab. 2 – Correlations matrix. Source: Author's estimation according to financial data of observed countries by using economic software Eviews.

	GROSS DOMESTIC PRODUCT	VOLUME OF IMPORTS	VOLUME OF EXPORTS	SWF ASSETS	GDP GROWTH RATE
GROSS DOMESTIC PRODUCT	1				
VOLUME OF IMPORTS	0.442	1			
VOLUME OF EXPORTS	0.823	0.408	1		
SWF ASSETS	0.119	0.260	0.060	1	
GDP GROWTH RATE	0.771	0.199	0.541	0.102	1

*Note: For example correlation between volume of exports and GDP is 0.823, increase together.*

### 3.3 Testing Hypothesis III.

In this section we focus on reserves. *Ipsissima verba*, China and other East Asian countries have responded to current account surpluses and capital inflows with reserve accumulation by the central bank rather than allowing these surpluses both to be self corrected and lodged in private hands through currency appreciation. China decreased to US 3,843tn in December of 2014 from US 3, 847tn in November of 2014. South Korea accumulated US 362370.10 in February of 2015. Nevertheless, countries have set up SWFs to manage these reserves.

The question is: How we can explain that China has massive foreign reserves? Basically China maintain the same exchange rate, on the one hand increase demand, on the other hand the central bank issue more of the domestic currency and purchase the foreign currency. That may resulted to an increase the sum of foreign reserves. Otherwise if the value of the currency

is being down (weak of currency), the domestic money supply is increasing (because money are being printed)= inflation (spiking of food prices).

First, we use data of 18 observed countries that set up SWF, especially following countries: Australia, Brazil, Canada, France, Hong Kong-China, Chile, Indonesia, Ireland, Italy, Korea, Malaysia, Mexico, New Zealand, Norway, Panama, Peru, Singapore, United States. Second, we determine the reliability at a 95% confidence level and determine level of the reliability of proportion of total reserves in observed countries of SWFs. Third, total reserves include gold in current US bn. We obtained data from OECD database, 2013.

Tab. 3 – Total reserves (US bn). Source: Author's estimation according to data from OECD, 2013. Source: Author's estimation according to data from OECD, 2013

Country	Gold Reserves US bn
Australia	52.837
Brazil	358.81
Canada	71.93
France	145.16
Hong Kong, China	3880.36
Chile	41.09
Indonesia	99.38
Ireland	1.635
Italy	145.72
Korea	345.69
Malaysia	134.85
Mexico	180.2
New Zealand	16.31
Norway	58.283
Panama	2.847
Peru	65.766
Singapore	277.797
United States	448.508
AVERAGE	351.509
STDEV	890.479
Tinv for $\alpha/2$	1.739
Tinv for $\alpha$	2.109

We use the TINV function that returns the value of t Student's t-distribution as a function of the probability and the degrees of freedom; in our case the number of degrees of freedom = N-1 where N is the number of values, and probability  $\alpha = 0.05$ .

The two-sided confidence interval can be determined from the relation:

$$\left( \bar{x} - t_{1-\frac{\alpha}{2}} \frac{s_1}{\sqrt{n-1}} \leq \mu \leq \bar{x} + t_{1-\frac{\alpha}{2}} \frac{s_1}{\sqrt{n-1}} \right) = 1 - \alpha \quad (1)$$

$$\left( 351.509 - 1.739 \frac{890.479}{\sqrt{17}} \leq \mu \leq 351.509 + 1.739 \frac{890.479}{\sqrt{17}} \right) = 1 - \alpha$$

$$(24.07 \leq \mu \leq 727.095) = 95\%$$

Results coming out from formula above show an acceptable range for levels of significance. On the other hand, it explains with at 95 percent of probability level that the proportion of total reserves in 18 observed countries is between US 24.07 and US 727.095 bn. Viewed in this light, countries that are large importers of gold will inevitably end up having a weaker currency when the price of gold rises. For example, countries that specialize in producing products made with gold, but lack their own gold reserves, will be large importers of gold.

To determine the left-hand interval for total reserves we use the following relationship:

$$P\left(\mu \geq \bar{x} - t_{1-\alpha} \frac{s_1}{\sqrt{n-1}}\right) = 1 - \alpha \quad (2)$$

$$P\left(\mu \geq 351.50 - 2.10 \frac{890.47}{\sqrt{17}}\right) = 0.95$$

$$P(\mu \geq 102.05) = 95\%$$

According to the results of this formula, the proportion of total reserves of observed countries will be more than US 102.05bn at 95% of probability level.

Then we formulate the hypothesis as follows:

***H<sub>0</sub>***: These are random deviations due to the selection of elements in the file Z,  $m = \mu$  .

***H<sub>1</sub>***: These are NOT random deviations due to the selection of elements in the file Z,  $m \neq \mu$  .

$$t = \frac{|\bar{x} - \mu|}{s} \sqrt{n} = \frac{351.509 - 102.05}{890.479} \sqrt{17} = 1.155 \quad (3)$$

$$t_{crit} = 2.10$$

The significance level of 0.05 and 17 degrees of freedom, the inverse two-sided t-distribution is calculated by TINV (0.05; 17) is 2.10. Ergo,  $t < t_{crit} \rightarrow$  we accept the null hypothesis, we came to the conclusion that there are random deviations due to the selection of observed funds in our file Z, in short, results are statistically significant.

## 4 CONCLUSION

In short, SWFs are important players in global financial markets due to their rapid growth US 7.071.2 tn in January 2015 according to the Sovereign Wealth Fund Institute. It is important to focus on background of their investments choices, wealth, financial fluctuations.

In fine, this paper presented econometric analysis. The econometric analysis clearly shows that 99.86 percent of changes of businesses are being explained by changes in Gross operating expense in the country (US mln), Shareholders' equity, SWF's assets (US mln), Balance Sheet-income: total assets (US mln), Total reserves (includes gold, current US). Moreover, high significant variables are gross operating expense, shareholders equity and gold reserves. On the other hand, countries with SWF attract attention from investors around the world, depends on industry, return, optimal strategy, Exchange rate, liquidity, risk, etc. As a result, we may say that companies can be chosen by SWF for locations, technologies that will help SWF region of origin. In other words, SWF's use their portfolios to achieve social goal, at the expense of the value and performance of the firm.

Then we examined that GDP of 44 countries with SWFs may be affected by Volume of imports of goods and services (% change), Volume of exports of goods and services (%

change), SWF assets (US bn) and GDP growth rate (annual %) at 84.49%. As we mentioned earlier, it is important to measure how export of oil, minerals, other commodities can affect GDP of country that set up SWF with purpose for future generations.

Third, we focused on reserves of 18 observed countries with SWFs, we determined the reliability of proportion of total reserves, especially we found that countries with SWFs hold gold reserves between 102.05 and 727.09 bn US. SWF's typically buy large quantities of gold when their country is experiencing high levels of inflation. The demand for gold increases during inflationary times due to its inherent value and limited supply. Anyway China holds huge U.S. dollar-denominated assets, but the U.S. dollar has been weakening on the exchange markets, and resulting in a relative loss of wealth. We may say that in the case of fluctuations in exchange rates, defense before inflation so a central banks must continually increase the amount of its reserves to maintain the same exchange rates.

In this regard of the econometric specification, time horizons, country groupings, influence of the size of an economy always plays a positive and highly significant role in affecting a country in terms of investments.

### **Acknowledgement**

Foremost, I would like to express my sincere gratitude to Prof. Zlatica Ivanicova from University of Economics in Bratislava for immense knowledge in econometrics.

## **THE DEPENDENCE OF ADDITIONAL PURCHASING OF BANKING PRODUCTS OR SERVICES ON THE LOYALTY OF BANKING CUSTOMERS IN THE CZECH REPUBLIC**

*Lenka Gabčová, Anna Chochořáková*

### **Abstract**

Examination of the dependence between the bank customers' loyalty and additional purchases of banking products and services is a current area of scientific research. Relatively few scientific studies try to quantify this relationship. The aim of this article was to examine and quantify the dependence of interest in purchasing additional banking products on the loyalty of banking customers. During the research in 2014, we have divided our respondents into two groups, loyal and disloyal respondents and have compared their attitudes according to the loyalty and additional purchases of banking products. The differences in their attitudes were analyzed by Pearson statistical test. The results clearly declared that loyal customers are more interested in services which are offered by their own bank, when considering what to do with their savings or investments, when taking mortgages or purchasing other banking products or services. According to the results of our research, the loyalty of banking customers is transformed with different types of intensity into potential additional purchases of banking products and services.

*Keywords: commercial bank, loyalty of banking customers, additional purchasing of banking products, share of wallet*

JEL Classification: G21

### **1 INTRODUCTION**

In the banking industry, where convenience and location are important, banks operate in between perfectly competitive and monopoly markets and are known as oligopolistic firms. Even though oligopolistic banks offer some level of differentiated products, the threat of competitors' reactions severely limits their ability to increase price when demand increases. Given this price rigidity, a bank's capability to increase revenues is contingent on the extent to which it can increase the quantity of products sold by attracting new customers and/or selling complementary products to its existing customers. Customers are more likely to purchase complementary products from the same firm when they face capability-based switching costs. (Brush, Dangol, and O'Brien, 2012)

Satisfied customer has a major importance for a current and future financial performance of the commercial bank. Korauš (2011) states that a satisfied customer stays loyal and for a bank to keep existing customer satisfied cost five times less money than to gain a brand new customer. Loyal customer is willing to pay higher price and to lure satisfied customer away to the competitor means for a bank to reduce the price of bank's product by 30%. Satisfied client represents a free form of advertising. He is inclined more to purchase more products from the bank. Satisfied customer gives a feedback to banks' employees in terms of sense of satisfaction and pride of their work and business.

The attention given to the banking customer should lead to a growing satisfaction level and to the satisfaction with partial activities of commercial bank, because it is generally assumed that

satisfied customer is loyal and his loyalty is reflected by higher level of additional purchases when compared to unsatisfied customer.

This study analyses the aspect of activities in commercial banks in detail.

## **2 THEORETICAL BACKGROUND**

Chakrabarty (2006); Manrai and Manrai (2007); Chavan and Ahmad (2013); Wruuck (2013); Chen, Liu, Sheu and Yang (2012); Chu, Lee, Chao (2012) analyzed various factors of customer satisfaction in regards to commercial banks.

Činjurevič, Tatič, and Avdič (2010) confirm the mediating role of satisfaction on the relationship among service quality dimensions and customer loyalty and therefore reconfirm the significance of customer satisfaction in the service setting. Karapete (2011) claims that results reported in his study suggest that all service quality dimensions have significant positive impacts on customer satisfaction. Interaction quality is the most important determinant of customer satisfaction, followed by service environment, reliability, and empathy. In this context Bilan (2013) points out that consumers don't want to play in any games, if they feel that anything goes wrong, they go away and choose another supplier.

According to De Matos, Henrique, and De Rosa (2013) customer loyalty is an important marketing variable for most of the companies, especially those working in more competitive markets. Authors emphasize that satisfaction is a relevant predictor of loyalty. More satisfied customers tend to be more loyal and to recommend the bank to other consumers. Hansen, Samuelsen, and Sallis (2013) more precisely specified that satisfaction has a strong positive effect on loyalty for high NFCs, but no effect for low NFCs (Some people engage in and enjoy thinking more than others, which is the core personality trait of interest in this study: need for cognition – NFC). According to Marimon, Yaya, Fa (2012) there is a direct link between the quality of services and the loyalty of a customer even in e-banking.

By Korauš (2011) loyalty is a state of mind, emotional attitude of customer to products and services, but is also rational assessment of previous experience with the business relationship.

Podl'a Terpstra and Verbeeten (2014) satisfied customers tend to be loyal and willing to purchase more of firm's services at higher prices. They also ascertained that customer satisfaction is positively associated with future customer revenues and customer value, especially in higher customer profitability segments (i.e., customer satisfaction is a value driver).

Cooil, Keiningham, Aksoy, and Hsu (2007) claims that changes in satisfaction are positively and nonlinearly related to the share of wallet a customer allocates to a particular service provider over time; specifically, the initial satisfaction level and the conditional percentile of change in satisfaction significantly correspond to changes in share of wallet. As stated by authors the relationship between satisfaction and share of wallet is moderated by both demographic and situational customer characteristics. In particular, income and length of relationship are significant predictors in the model. Both income and length of relationship negatively moderated the relationship between changes in satisfaction and share of wallet. There is no evidence that age is a positive moderator (satisfaction and share of wallet). Education is not a predictor.

Keiningham, Gupta, Aksoy, and Buoye (2014) make reference to very interesting idea. As claimed by authors, academic research consistently finds that there is a positive, statistically significant relationship between satisfaction and a host business outcomes such as customer retention, share of wallet, referrals and stock market performance. The problem is that the

relationship between customer satisfaction and customer spending behavior is very weak. Our research finds that changes in customers' satisfaction levels explain less than 1% of the variation in changes in their share of category spending. The relationship is statistically significant, but it is not very managerially relevant.

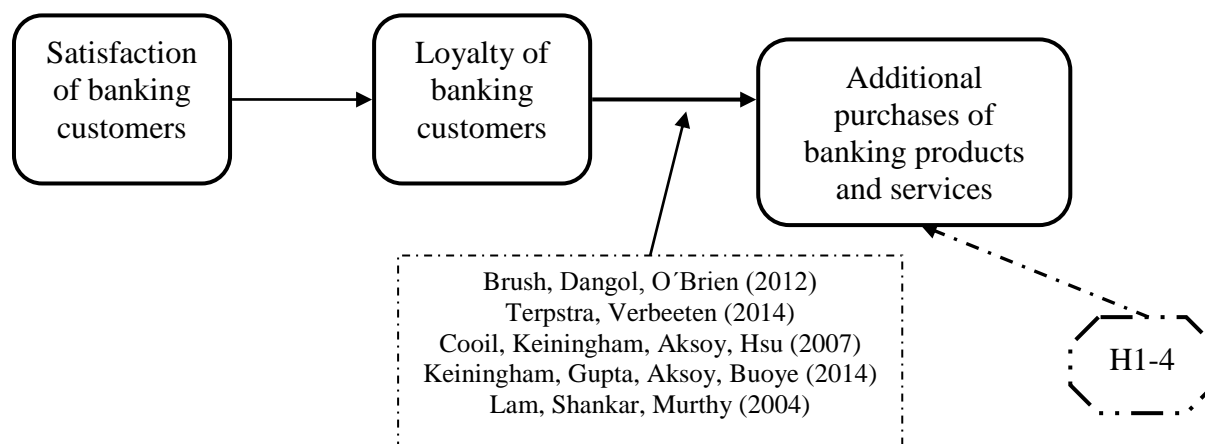

More likely it is possible to agree with the results of Lam, Shankar, Murthy (2004) studies, in which the authors claim that whereas the customer satisfaction completely influence his recommendation to others, it only partially affects his tendency to re-purchase services again. Another factor enters into decision making process and perception of the value of the services when deciding to re-purchase services. With regards to this factor, the provider can devote efforts to increase the value perceived by the customer to enhance customer satisfaction. It also can provide attention to other values that can affect the customer satisfaction, such as fair and equal approach. If a company wants to attract new customers, this should be focused primarily on customer satisfaction, because that satisfaction is the main reason that crucially affects the customers' recommendation to his friends. If the company wants to keep the customer and do not want to lose him, it is important to monitor the perception value of offered services.

### 3 OBJECTIVES, METHODOLOGY AND DATA

The aim of this paper was to examine and quantify the dependence of additional purchases of bank products on customers' loyalty.

On the basis of the qualitative analysis, we created *Conceptual model*, which you can find on Fig. 1.

Fig.1 – Conceptual model of loyalty and additional purchases of customers. Source: own research.

In 2014 we conducted a quantitative research of satisfaction, loyalty and additional purchases in Czech banking sector. We used questionnaire survey on a sample of 459 respondents, of which 44% were men and 56% were women. The age structure of those respondents was as follows: 39% of respondents were aged under 30 years, 44% were aged from 31 to 50 years and 17% of them were customers over 50. The education level of respondents was as follows: 3% had primary education, 54% had secondary education and 43% were university educated bank customers.

The results of Brush, Dangol, O'Brien (2012), Terpstra and Verbeeten (2014), Cooil, Keiningham, Aksoy, and Hsu (2007), Keiningham, Gupta, Aksoy, Buoye (2014), Lam, Shankar, Murthy (2004) research has inspired us to determine these hypotheses:

*H1: Loyal customers are more interested in services of their own bank when deciding to invest money in financial markets in comparison to disloyal customers.*

*H2: Loyal customers are more interested to create deposits in their own bank compared to disloyal customers.*

*H3: Loyal customers are more interested in taking mortgages from their own bank in comparison to disloyal customers.*

*H4: Loyal customers are more interested in additional purchasing of banking products and services in their own bank compared to disloyal customers.*

We examined the connection between loyalty and additional purchasing of banking products. Our procedure was as follows. On the basis of the questionnaire results we divided the whole set of respondents into two groups. The first group consisted of respondents who on the following statement: *I gladly recommend my bank to my friends*, indicated assent (we called them loyal customers). The second group consists of respondents who stated dissenting opinion (disloyal customers). Respondents who did not have an opinion were excluded.

Established scientific assumptions in each table were examined through Pearson statistics. P-value less than 5% leads to the rejection of the null hypothesis. Part of the quantitative analysis is the use of indicators and descriptive statistics such as weighted arithmetical average and the percentage figures.

## **4 RESULTS AND DISCUSSION**

The level of customers' satisfaction in the banking business is in many countries quiet different. For example, in United Kingdom in 2012, top of the table for customer satisfaction were First Direct, The One Account and the Co-Operative Bank with 86%, 80% and 79 %. Respectively Santander and Halifax scored the lowest results with just 46% and 48% of their customers saying they were satisfied - well below the average score of 62%. (www.dailymail.co.uk). McKinsey & Company (2012) states that customer satisfaction scores for retail banks in USA in 2011 were 8.23 out of a total of 10 points. Customer satisfaction in 2011 compared with 2010 has slightly decreased, but up to 39% of clients stated in this research that their bank did nothing about increasing their satisfaction last year. According to results of our research in Czech Republic, the overall satisfaction of clients was around 62 % in 2012. (Belás, Burianová, Cipovová, Červenka, 2013) The overall satisfaction of banks' customers in Slovakia was 61% in 2012. (Belás, Holec, Homolka, 2013)

According to the results of our research, the overall satisfaction of clients of commercial banks was at the level of 66.29% in 2014, and 16.40% of the customers reported a negative attitude and 17.13% of respondents could not decide. We can therefore conclude that the overall satisfaction rate of bank customers has slightly increased in the past years.

Table 1 reflects the results to one of the questions where we asked, if clients recommend their bank to friends.

Tab. 1 – Results about the loyalty of Czech banking clients Source: own research.

I gladly recommend my bank to my friends.	CR 2014 in %
1. agree (loyal clients)	39.18
2. disagree (disloyal clients)	25.28
3. do not know (excluded from the research)	35.54

According to the results which are listed in the Table 1 we have divided the whole sample of respondents into two parts. The first part was created by respondents whose answer was No. 1 (named as loyal customers). Second part were respondents who have chosen No. 2 (disloyal customers) and those who have chosen No.3 were excluded from further research.

Tables 2 – 5 reflect the results to the question about additional purchases of banking products.

Tab. 2 – Potential interest in investments in the financial market. Source: own research.

If I am interested in investments in the financial market, I will use services in my bank.	Loyal clients CR 2014 in %	Disloyal clients CR 2014 in %	p-value
1. agree	48.84	6.31	<b>&lt;0.01</b>
2. disagree	19.77	63.06	<b>&lt;0.01</b>
3. I do not know	31.40	30.63	0.88866

H1 has been confirmed. Loyal customers are more interested in their banks' services when considering where to invest their savings in comparison to the disloyal customers (p-value<0.01). The intensity of this interest was quite low, only 48.84% of banking clients have confirmed that they would invest in their bank.

Tab. 3 – Generating deposits in the bank. Source: own research.

If I save up some money I will put them to my bank.	Loyal clients CR 2014 in %	Disloyal clients CR 2014 in %	p-value
1. agree	71.51	37.84	<b>&lt;0.01</b>
2. disagree	15.12	52.25	<b>&lt;0.01</b>
3. I do not know	13.37	9.91	0.38430

H2 has been confirmed. Loyal customers are more interested in generating deposits in their own bank in comparison to disloyal clients (p-value<0.01). In this case, the intensity of the interest to save in their bank was relatively high, 71.51% loyal customers has confirmed that they would do it. This phenomenon confirms that no matter the interest rate in other banks would be, loyal and satisfied customers would not change their banks.

Tab. 4 – Potential interest in the mortgage. Source: own research

If I wanted to take a mortgage, I would choose products and services from my bank.	Loyal clients CR 2014 in %	Disloyal clients CR 2014 in %	p-value
1. agree	66.86	32.43	<b>&lt;0.01</b>

2. disagree	9.88	36.94	<b>&lt;0.01</b>
3. I do not know	23.26	30.63	0.16758

H3 has been confirmed. We found out that loyal customers are more interested in mortgages from their bank compared to disloyal customers (p-value<0.01). 66.86% of clients said that they would be interested in taking mortgages.

According to a research by Ernst & Young (2012), almost 50% of Czech respondents bought mortgages off their main bank. There could be also noticed an intensive campaign of almost all banks to win new clients from the competition in the banking sector. However, it might be more appropriate to take better care of existing clients and to know how to offer them the product at the right time.

Tab. 5 – Potential interest in additional banking services. Source: own research.

I am considering if to choose any additional banking products and services.	Loyal clients v % CR 2014	Disloyal clients v % CR 2014	p-value
1. agree	56.40	8.11	<b>&lt;0.01</b>
2. disagree	13.37	60.36	<b>&lt;0.01</b>
3. I do not know	30.23	31.53	0.81810

H4 has been confirmed. Loyal customers had more interest in using additional banking products and services in their bank compared to disloyal clients (p-value<0.01). However, the ratio of their interest was quite small.

According to our results, the differences in the intensity are transformed into potential purchases of additional banking products. The highest potential interest was spotted by the question No.3 and No. 4 where we discussed deposits and mortgages. The reason for this could be the fact that these products are the most common ones. Customers were not as interested in financial investments or any additional banking products.

In this context Terpstra and Verbeeten (2014) claim that customers tend to acquire low risk assets first (saving account). In due time, they acquire more risky assets (such as pension fund, life insurance, investment trusts, shares, and bonds). It is likely that the more risky asset categories provide more revenues for financial firms. A potential explanation for our findings is therefore that satisfied customers purchase more (high margin, high risk) services, while dissatisfied customers reduce their product portfolios and eventually discard the low margin, low risk asset product (checking and savings accounts).

According to traditional trade schemes it should apply that satisfied customers are buying more products from their own bank with which they have a long-term relationship based on win-win strategy. The results of our research did not confirm this trend. The data, which were obtained in Czech and Slovak commercial banking trends, suggest that satisfied customers are buying a less fewer products than dissatisfied customers. (Belás, Cipovová, Demjan, 2014)

## 5 CONCLUSION

In the conditions of intense competition in the banking market is satisfaction and loyalty of bank customers significant attribute of the current financial performance of commercial banks and an important prerequisite for future growth.

Retail banking is a typical service industry, in which customers frequently become loyal only after some years of doing business with the same bank. Banking services are contract-based and usually entail a long term relationship between a customer and a bank. There is a reason to believe that the banking industry faces new challenges when the traditionally stable relationships are challenged by deregulation and increased competition. (Činjarevič, M., Tatič, K., Avdič, A., 2010)

The results of our research declare that loyal customers are more interested in the services of their own banks when considering savings, investments in the financial market, mortgages or purchasing other banking products or services. According to the results of the research, loyalty of clients is transformed into potential additional purchases with different strength of intensity. The most interesting products and services for respondents were mortgages and deposits. The level of interest in investments and purchasing any other additional banking products was quite low.

Our study has some limitations. However, the study could be perceived as a good inspiration and motivation for managing relationships with bank customers.

The further research will be focused on theoretical possibilities of the quantification dependence of additional purchases of banking services or products on the loyalty of bank customer.

## **EFFICIENCY OF CZECH AND SLOVAK INSURANCE COMPANIES EVALUATED BY DEA MODELS**

*Eva Grmanová*

### **Abstract**

The paper compares the efficiency of commercial insurance companies in Slovakia and the Czech Republic on the common insurance market. The aim was to express the efficiency score of the insurance companies by two models and divide the insurance companies into groups based on these two models. The resulting comparisons and classification may be part of benchmarking and may have practical benefits for the insurance companies. In addition to the relative comparison of their efficiency, it will provide information on the need to modify their indicators and may lead to improving their management performance. DEA models were used to evaluate efficiency. Five out of the thirty-two insurance companies were efficient. On the Czech insurance market, three insurance companies were efficient: BNP Paribas Cardif Pojišťovna, a.s.; Kooperativa, pojišťovna, a.s.; Komerční pojišťovna, a.s.. On the Slovak insurance market, two insurance companies were efficient Poist'ovňa Poštovej banky, a.s.; Rapid life životná poisťovňa, a.s.. The result of using the cluster analysis and factor analysis is the formation of two other clusters. One cluster is formed by five efficient insurance companies and ten insurance companies with above average values of input-oriented efficiency scores and below average values of output-oriented efficiency scores. They would become efficient by less radical modifications of their indicators.

*Keywords: insurance market, commercial insurance companies, benchmarking, DEA models, input-oriented BCC models, output-oriented BCC models*

### **1 INTRODUCTION**

Insurance market belongs to a financial system. Financial system is the heart of each market economy. The international concept of insurance (and especially reinsurance) operations brings a certainty and helps to balance the economic results. (Nečas & Čejková, 2014)

Commercial insurance companies are important actors on the insurance market. Fundamental role of the insurance companies is to relay the risk of their clients. (Majtanová et al., 2009) Strong competition forces them to seek opportunities for improving their position on the market. One possible way of determining increasing competitiveness is analysing the efficiency of insurance companies in relation to other insurance companies.

The efficiency of insurance companies can be evaluated using several quantitative methods. One possible approach is using Data Envelopment Analysis (DEA) models. There are several primary and alternative DEA models. In our analysis we will use radial models.

The application of DEA models may be part of benchmarking and may have practical benefits for the insurance companies. In addition to the relative efficiency comparison, it will also provide information on the need to modify their indicators and may lead to improving their management performance.

The characteristic of DEA models were introduced by Charnes, Cooper, and Rhodes (1978). In 1984 the BCC model under condition of variable returns to scale was drawn up by Banker, Charnes, and Cooper (1984).

In the Czech Republic and Slovakia several scientists deal with the model of data envelopment analysis. Jablonský and Dlouhý (2004) in *Models for Evaluation of Efficiency of Production Units* focused on the specification of basic and alternative models. Stavárek (2005) evaluated bank efficiency in the Group of Visegrad countries. Repková (2013) evaluated bank efficiency of the Czech Republic.

From the extensive research devoted to the efficiency of insurance companies, the results of Diaconis (2001) should be mentioned. Diaconis compiles the efficiency of 431 insurance institutions from six European countries, namely from France (64 insurance companies), Germany (121 insurance companies), from Italy (27 insurance companies), the Netherlands (31 insurance companies), from Switzerland (22 insurance companies) and from Great Britain (166 insurance companies) and published them in *The Efficiency of UK General Insurance Companies*.

At the present there are several authors in the SR and CR devoting their attention to insurance market. Experts on the insurance market are Čejková and Majtanová. Čejková deals with the specification of the insurance market and insurance in the Czech Republic and in Slovakia. Majtanová is devoted to the theory and practice in the insurance industry.

## **2 AIMS AND METHODS**

In the analysis we focus on the efficiency of commercial insurance companies in Slovakia and the Czech Republic on the common insurance market in terms of production. Our aim is to express the efficiency score of insurance companies using two efficiency models and to divide insurance companies into groups based on these two models.

We will focus on expressing the efficiency score assuming there are variable returns to scale (BCC). We will apply

- input-oriented BCC models
- output-oriented BCC models.

The scores expressed by both models will enable us to assess the status of insurance companies in terms of inputs and outputs. Their relative position in the models may vary. However, using both models is important due to the complexity of evaluating their position on the insurance market.

In this paper, we focus on the efficiency of production activities of insurance companies. The main production income of insurance companies is earned premiums. The basic costs of commercial insurance companies are costs of claims and benefits and operational expenses. Therefore, inputs in the models are the costs of claims and benefits and operational expenses, the output are earned premiums. We will use the EMS program to express the efficiency score. The values will be taken from the database of the Czech Insurance Association (2013) and annual reports of individual insurance companies (2013).

The resulting values of efficiency scores will be subject to further analysis. Our aim will be to divide all analysed insurance companies into groups based on the similarity of their determined efficiency scores. We expect to find a group of insurance companies which will have to perform a more radical modification of their inputs and outputs in order to become efficient, and a group of insurance companies requiring a less radical modification of their

inputs and outputs. The resulting values will be part of benchmarking. We will evaluate the similarity of insurance companies based on cluster analysis. The output will be a graphic representation in form of a dendrogram.

## 2.1 DEA Models

DEA models belong to quantitative models designed to express the relative efficiency of the analysed subjects. The subjects analysed by DEA models are called Decision Making Units. Decision Making Unit is to be rated as fully efficient on the basis of available evidence if and only if the performances of other Decision Making Units does not show that some of its inputs or outputs can be improved without worsening some of its other inputs or outputs. (Bogetoft & Otto, 2011)

At the beginning of the analysis indicators of these Decision Making Units are divided into two groups - inputs and outputs. Inputs meet the minimization criterion and outputs meet the maximization criterion. Assuming there are variable returns to scale, radial models known as BCC models are used. Models based on linear programming transform multiple inputs into multiple outputs. They construct non-parametric data envelopment, which is convex. The Decision Making Units that are part of the data envelopment are efficient and their efficiency score is equal to one or 100%. The Decision Making Units that are not part of the data envelopment are called inefficient. The efficiency of inefficient Decision Making Unit is expressed by the efficiency score in relation to data envelopment. (Grmanová, 2010)

### BCC Model Oriented on Inputs

Suppose we have  $n$  homogeneous Decision Making Units  $U_1$  and  $U_n$  and we observe  $r$  outputs and  $m$  inputs. We will denote the input matrix  $\mathbf{X} = \{x_{ij}, i = 1, \dots, m, j = 1, \dots, n\}$ . The output matrix will be denoted  $\mathbf{Y} = \{y_{ij}, i = 1, \dots, r, j = 1, \dots, n\}$ . The dual BCC model oriented on inputs in matrix form has a shape

$$\min z = \theta_q - \varepsilon(\mathbf{e}^T \mathbf{s}^+ + \mathbf{e}^T \mathbf{s}^-), \quad (1)$$

subjects to  $\mathbf{X}\lambda + \mathbf{s}^- = \theta_q \mathbf{x}_q,$

$$\mathbf{Y}\lambda - \mathbf{s}^+ = \mathbf{y}_q,$$

$$\mathbf{e}^T \lambda = 1,$$

$$\lambda, \mathbf{s}^+, \mathbf{s}^- \geq \mathbf{0},$$

(Banker, Charnes, & Cooper, 1984)

where  $\theta_q$  is the efficiency score of the Decision Making Unit  $U_q$ ,  $\mathbf{s}^+, \mathbf{s}^-$  are the deviation variables,  $\lambda$  is the matrix of weights,  $\mathbf{e}^T = (1, \dots, 1)$ ,  $\varepsilon$  is the infinitesimal constant.

Target values of inputs and outputs to achieve efficiency can be obtained in one of two ways:

1.  $\mathbf{x}_q' = \mathbf{X}\lambda^*$ ,  $\mathbf{y}_q' = \mathbf{Y}\lambda^*$ , where  $\lambda^*$  is the vector of optimal values of weights calculated by the model, and

2.  $\mathbf{x}_q' = \theta_q^* \mathbf{x}_q - \mathbf{s}^{-*}$ ,  $\mathbf{y}_q' = \mathbf{y}_q + \mathbf{s}^{+*}$ , where the symbols labelled \* are vectors of optimal variable values in the input-oriented BCC model. (Jablonský & Dlouhý, 2004)

### BCC Model Oriented on Outputs

Suppose we have  $n$  homogeneous Decision Making Units  $U_1$  and  $U_n$  and we observe  $r$  outputs and  $m$  inputs. We will denote the input matrix  $\mathbf{X} = \{x_{ij}, i = 1, \dots, m, j = 1, \dots, n\}$ . The output

matrix will be denoted  $\mathbf{Y} = \{y_{ij}, i = 1, \dots, r, j = 1, \dots, n\}$ . The dual BCC model oriented on outputs in matrix form has a shape

$$\max \quad g = \phi_q + \varepsilon(\mathbf{e}^T \mathbf{s}^+ + \mathbf{e}^T \mathbf{s}^-), \quad (2)$$

subjects to  $\mathbf{X}\boldsymbol{\lambda} + \mathbf{s}^- = \mathbf{x}_q$ ,

$$\mathbf{Y}\boldsymbol{\lambda} - \mathbf{s}^+ = \phi_q \mathbf{y}_q,$$

$$\mathbf{e}^T \boldsymbol{\lambda} = \mathbf{1},$$

$$\boldsymbol{\lambda}, \mathbf{s}^+, \mathbf{s}^- \geq \mathbf{0},$$

where  $\phi_q$  is the efficiency score of the Decision Making Unit  $U_q$ ,  $\mathbf{s}^+, \mathbf{s}^-$  are the deviation variables,  $\boldsymbol{\lambda}$  is the matrix of weights,  $\mathbf{e}^T = (1, \dots, 1)$ ,  $\varepsilon$  is the infinitesimal constant.

Target values of inputs and outputs to achieve efficiency can be obtained in one of two ways:

1.  $\mathbf{x}_q' = \mathbf{X}\boldsymbol{\lambda}^*$ ,  $\mathbf{y}_q' = \mathbf{Y}\boldsymbol{\lambda}^*$ , where  $\boldsymbol{\lambda}^*$  is the vector of optimal values of weights calculated by the model, and

2.  $\mathbf{x}_q' = \mathbf{x}_q - \mathbf{s}^{-*}$ ,  $\mathbf{y}_q' = \phi_q^* \mathbf{y}_q + \mathbf{s}^{+*}$ , where the symbols labelled \* are vectors of optimal variable values in the output-oriented BCC model. (Jablonský & Dlouhý, 2004)

### **Multivariate Exploratory Techniques**

Multivariate exploratory techniques include principal component analysis, factor analysis, cluster analysis, canonical correlation analysis, etc.

The aim of the principal component analysis is to simplify the description of a group of linearly interdependent or correlated variables. It is a method of linear transformation of the original variables into new, uncorrelated variables, which are called principal components. Each principal component is a linear combination of the original variables. Principal components are ranked according to decreasing variance.

The main focus of the factor analysis is to reduce redundant information in multiple correlated variables. The aim of the method is to describe latent properties of the structure of a set of variables using a small number of mathematically constructed characteristics. (Nábělková & Hitka, 2007) These characteristics are uncorrelated and are called factors or dimensions. The output of the cluster analysis is the estimated values of factor loadings and the estimated factor score. Factor loadings of variables (saturation) express the correlation between the variables and factors. Based on the values of the factor loadings it is possible to determine a group of variables for each factor that correlate the most with it. The factor score estimation is the estimation of values that the factors acquire for individual objects. If the factors poorly correlate with a greater number of original variables, their interpretation is made impossible. The solution is factor rotation. There are several factor rotation techniques. It is recommended to use the technique providing the simplest interpretation.

The aim of the principal component analysis and factor analysis is to reduce the dimensionality of a group of data. The main difference between them is that principal component analysis explains the variability of variables and factor analysis explains the correlation between variables. In contrast to principal component analysis, by factor analysis we try to explain the dependence of variables. (Meloun, Militký, & Hill, 2012) Principal component analysis explains all variability between original variables. Factor analysis explains only the variability which is common for all variables. (Rimarčík, 2007) The

disadvantages of factor analysis include for example factor uncertainty, where each object can be quantified by various factor scores.

Cluster analysis belongs to multi-dimensional exploration techniques, by which subjects are grouped into groups - clusters - based on their similarities and differences. The clusters are formed in a way to achieve the greatest possible similarity among subjects within a cluster and at the same time to achieve the greatest difference between subjects in different clusters. The distance between the objects is expressed by various ways. One of them is the Euclidean distance. (Minařík, Borůvková, & Vystrčil, 2013)

For an  $m$ -dimensional space, the Euclidean distance  $d_{AB}$  between  $A = x_1, x_2, x_3, \dots, x_m$  and  $B = y_1, y_2, y_3, \dots, y_m$  will express

$$d_{AB} = \sqrt{\sum_{k=1}^m (y_k - x_k)^2}. \quad (3)$$

Important assumption of the cluster analysis is the use of standardised variables. Based on the organisation of objects into clusters, we distinguish hierarchical and non-hierarchical methods of cluster analysis. Hierarchical methods are based on individual objects and by their linking the number of clusters decreases. They lead to a tree structure depicted as a dendrogram. There are several methods of linking – Single Linkage, Complete Linkage, Unweighted Pair-group Average, etc. Non-hierarchical methods do not produce a tree structure. They link objects into a non-hierarchical system of clusters, which are formed by successive decomposition of a group of objects into sets. The first step is the choice and selection of the seed cluster, which is the initial cluster centre.

Using cluster analysis is associated with risks. These may include, for example, that the number of clusters is the result of the analyst's consideration. Clusters may not arise. Various clustering methods can lead to different results.

### **3 RESULTS**

Our paper is focused on the analysis of thirty-two commercial insurance companies on the common Slovak and Czech insurance market. Out of this number, seventeen insurance companies were from the Czech insurance market and fifteen insurance companies were from the Slovak insurance market. We used the values found in annual reports of these insurance companies (2013) and in the database of the Czech Insurance Association.

We expressed descriptive statistics of the outputs and inputs and compared their variability using the coefficient of variation. The values are shown in Table 1. The arithmetic mean was influenced mainly by high values of a small number of insurance companies. The greatest variability expressed by the coefficient of variation had the claims incurred. Operational expenses had the lowest variability. The expression of descriptive statistics shows that the distribution of the probability of inputs and outputs is asymmetrical.

Tab. 1 – Descriptive statistics analyzed parameters. Source: own calculations in Statistica

	Arithmetic mean of thousands EUR	Median of thousands EUR	Standard deviation	Coefficient of variation in %
Earned premiums	189354,1	110700,5	234704,2	124,0
Claims incurred	127474,6	67378,0	168964,8	132,5
Operational expenses	52617,7	27444,5	60733,8	115,4

### 3.1 Efficiency Scores by Input and Output - Oriented BCC Models

In the next step

- we expressed the efficiency score in the input-oriented BCC model;
- we ranked insurance companies based on their efficiency score in the input-oriented BCC model;
- we expressed efficiency score in the output-oriented BCC model;
- we ranked insurance companies based on their efficiency score in the output-oriented BCC model.

The resulting values are shown in Table 2. Five out of the thirty-two insurance companies were efficient. On the Czech insurance market, three insurance companies were efficient: BNP Paribas Cardif Pojišťovna, a.s.; Kooperativa, pojišťovna, a.s.; Komerční pojišťovna, a.s.. On the Slovak insurance market, two insurance companies were efficient Poist'ovňa Poštovej banky, a.s.; Rapid life životná poisťovňa, a.s.. Interestingly, the insurance company Allianz – Slovenská poisťovňa, a.s., which has long been one of the leaders on the insurance market, was not efficient. Similarly, KOOOPERATIVA poisťovňa, a.s. Vienna Insurance Group, which also has long belonged to the leaders on the Slovak insurance market, was not efficient. A total of twenty-seven insurance companies were not efficient. The efficiency score in the input-oriented models was less than 100%. The value of the efficiency score determines the percentage to which the insurance company has to reduce its inputs in order to become efficient. The higher the value of the efficiency score, the more favourable for the insurance company.

The efficiency score in the output-oriented models was greater than 100%. The value of the efficiency score determines to what percentage the insurance company has to increase its outputs in order to become efficient. The lower the value of the efficiency score, the more favourable for the insurance company. The ranking of insurance companies on the common insurance market was determined based on both efficiency scores.

Tab. 2 – Efficiency score by BCC models. Source: own calculations in EMS

	Insurance companies	Efficiency score in the input-oriented model (%)	Ranking	Efficiency score in the output-oriented model (%)	Ranking
1	Allianz pojišťovna, a.s.	74,4	13	118,5	10
2	AXA životní pojišťovna a.s.	79,5	10	124,8	11-12

3	BNP Paribas Cardif Pojišťovna, a.s.	100,0	1-5	100,0	1-5

30	Union poisťovňa, a.s.	47,6	22	210,0	22
31	UNIQA poisťovňa, a.s.	51,1	20	189,4	19
32	Wüstenrot poisťovňa, a.s.	51,8	19	192,2	20

*Note: MetLife Amslico poisťovňa, a.s., Rapid life životná poisťovňa, a.s. did not publish prescribed premiums but earned premiums in their annual premiums.*

### **3.2 Similarity of Insurance Companies**

In respect of the efforts to develop typologies of insurance companies on the basis of their achieved efficiency scores, we applied the methods factor analysis and cluster analysis. Due to the asymmetric probability distribution of the variables, we used log-normal transformation. In factor analysis, we used principal components as the method of extracting.

The result was the factor explaining 88.68% of the variance. The own number was 1.773569. Factor loading of the input-oriented efficiency score was 0.941692. Factor loading of the output-oriented efficiency score was -0.941692. Values of the factor score for each insurance company analysed, designated by a number as in Table 2, are shown in Table 3.

Tab. 3 – Factor scores in factor analysis. Source: own calculations in Statistica

	1	2	3	4	5	6	7	8	9	10	11
Factor score	0,749	0,767	1,428	0,934	-0,385	-0,383	-0,413	-0,625	0,330	-1,704	1,428

Tab. 3 – Factor scores in factor analysis - continuation of the table. Source: own calculations in Statistica

	12	13	14	15	16	17	18	19	20	21	22
Factor score	1,428	0,998	-1,326	0,818	-0,783	-0,680	1,040	0,551	-0,394	-1,131	-1,467

Tab. 3 – Factor scores in factor analysis - continuation of the table. Source: own calculations in Statistica

	23	24	25	26	27	28	29	30	31	32
Factor score	-1,056	0,431	-1,157	0,642	1,428	-1,160	1,428	-0,749	-0,492	-0,495

Positive values of the factor score had insurance companies that achieved above-average value of the input-oriented efficiency score and below-average value of the output-oriented efficiency score. They would become efficient by less radical modifications of their indicators. Negative values of the factor score had insurance companies that achieved below-average value of the input-oriented efficiency score and above-average value of the output-oriented efficiency score. The smallest difference in values was in the case of UNIQA poisťovňa, a.s, and Wüstenrot poisťovňa, a.s. The lowest value was achieved by ING životní poisťovňa.

We used cluster analysis to analyze similarity. We applied hierarchical clustering in order to create a certain typology of insurance companies with respect to the achieved efficiency scores. For linking clusters we used the method Single linkage (Nearest neighbour), where the distance between two clusters is determined as the distance between the two closest members.

The aim was to determine the similarity of insurance companies based on their efficiency scores and divide insurance companies into groups. The results are shown in Figure 1. Insurance companies are designated by serial numbers listed in Table 2.

Fig. 1 – Dendrogram. Source: own processing in Statistica

The result of using the cluster analysis is the formation of two other clusters. One cluster is formed by five efficient insurance companies and ten insurance companies with above average values of input-oriented efficiency scores and below average values of output-oriented efficiency scores. They would become efficient by less radical modifications of their indicators. This group includes insurance companies which were able to better transform their inputs into outputs. On the Czech insurance market it is the insurance companies Allianz pojišťovna, a.s.; AXA životní pojišťovna; Česká pojišťovna, a.s.; MAXIMA pojišťovna, a.s.; Pojišťovna České spořitelny, a.s., Vienna Insurance Group. The cluster includes also the Hasičská vzájemná pojišťovna, a.s.. On the Slovak insurance market it is the insurance companies Allianz - Slovenská poisťovňa, a.s.; ČSOB Poisťovňa, a.s; KOOPERATIVA poisťovňa, a.s. Vienna Insurance Group; Poisťovňa Cardif Slovakia, a.s.. The second cluster is formed by insurance companies which are not efficient and do not belong to the former group. These insurance companies would become efficient by a more radical modification of their inputs and outputs. Special positions in this cluster have ING Životní pojišťovna N.V., pobočka pro Českou republiku, that achieved the least value of the efficiency score in the input-oriented model.

The comparison showed that this insurance company should focus mainly on increasing its output-earned premiums.

By comparing the output of factor analysis and cluster analysis we can conclude that the two main clusters of insurance companies are formed by the same insurance companies. Insurance companies with the smallest Euclidean distance in the cluster analysis have the smallest differences between factor scores in the factor analysis. The insurance company that has the efficiency scores the least similar to other insurance companies in the cluster analysis has the lowest values of the factor score in factor analysis.

## 4 DISCUSSION

DEA models are very useful in assessing efficiency. Their application in research is extensive. This is evidenced by many scientific studies. A part of such studies deals with their application for the insurance industry. The survey focused on assessing efficiency is, in

addition to quantitative methods, often supplemented by statistical methods. Examples of such methods are tests aimed at testing the differences in the probability distribution and thus detecting differences between various groups. For example, Diaconis (2001) used the Kruskal-Wallis test. In our paper, we focus on the application of the data envelopment analysis models supplemented by the cluster analysis, which belongs to multivariate statistical methods.

We focused on the use of these methods in the insurance industry, especially in view of benchmarking. We used a combination of approaches – input-oriented BCC models, output-oriented BCC models and statistical methods.

When assessing effectiveness, however, several kinds of quantitative methods can be used. Each application has its specific advantages and disadvantages. One very important aspect is controllability. On a very specific level, ease of interpretation is also important. (Bogetoft & Otto, 2011) The advantage of the BCC models is that they provide information on how to adjust inputs or outputs to make the Decision Making Unit effective. Interpretation in this case is ease.

Their disadvantage BCC models is that they can not effectively eliminate the negative impact of random errors and the results are highly affected by the choice of inputs and outputs.

## **5 CONCLUSION**

In this paper, we focused on assessing the efficiency of insurance companies on the common Slovak and Czech insurance market.

Expressed efficiency scores were used to rank insurance companies on the insurance market on the basis of their transformation of inputs into outputs. When ranking the insurance companies, it is important to express their ranking in input-oriented BCC models and in output-oriented BCC models. By performing cluster analysis it is possible to obtain a broader view of the benchmarking of these insurance companies.

## **COMPARISON OF CZECH AND SLOVAK PUBLIC ADMINISTRATION APPROACH TO THE CONCEPT OF EU COHESION POLICY IMPLEMENTATION FOR THE PROGRAMMING PERIOD 2014 - 2020**

*Oldřich Hájek, Lenka Smékalová*

### **Abstract**

Programming period of the European Union for the years 2007 - 2013 enabled the Czech Republic to utilize up to EUR 26.7 billion within the frame of EU economic and social cohesion policy. Similarly, the Slovak Republic was able to support its development in this period by using up to EUR 11.7 billion. During the implementation of this coordinated EU policy public administration institutions in the Czech and Slovak gained substantial experience. The aim of this article is to present the approaches of the Czech and Slovak public administration to the concept of implementation of EU cohesion policy for the programming period 2014 - 2020. This is once more a great opportunity for the Czech and Slovak governments as in this period. The above mentioned countries may gain up to EUR 23.9 billion and EUR 15.5 billion respectively in order to enhance their own development.

*Keywords: public administration, European Union Cohesion Policy, EU Structural Funds*

JEL Classification: O18, R12, R58

### **1 INTRODUCTION**

Cohesion Policy of the European Union or the policy of economic and social cohesion of the EU has been for many years well-established coordinated policy at the European level. Member States and their governments actively participate in the implementation of this policy and within its framework present various types of development projects. During the seven year lasting programming period it is possible to draw funds from the structural funds or other instruments to support these projects. Governments of the Czech and Slovak Republic were confronted with the economic and social cohesion of the EU before the accession year of 2004 and the success of the politicians in acquiring necessary funds for development represents a part of their public popularity (Horváth and Machyniak, 2014). The pre-accession period, which denotes the meantime between the full membership of these countries in the EU and the date of application, these countries could benefit from EU pre-accession funds. These specific tools were aimed at support of projects including the implementation of European legislation, i.e. *acquis communautaire*, into national legislation, also projects concerning transport and the environment (see e.g. Sedelmeier 2011, Scherpereel 2010). In the period before joining the EU fundamental changes had to take place in the primary and secondary sector, which, especially after the accession to the EU, faced tougher competition in an open EU market (Baldwin, Francois and Portes 1997, Fuller 2002). A large part of the funds from the pre-accession instruments was oriented on the training of employees of public administration institutions, transfer of experience and examples of good practice in the implementation of EU policies within the local and national conditions, and in twinning programmes, aimed at increasing the skills of the individual officials. PHARE (Poland and Hungary Aid for Restructuring of the Economy), ISPA (Instrument for Structural Policies for Pre-Accession) and SAPPARD (Special Accession Programme for Agriculture and Rural

Development) are among the most important pre-accession instruments in the period ending by the 2004 accession of the Czech and Slovak Republic (Bízikova et al. 2004, Marek and Baun 2002, Kluvánková-Oravská 2004). Implementation of these pre-accession instruments significantly eased the preparation of the Czech and Slovak Republic accession to the European Union and helped them emerge as a part of Visegrad convergence club as identified by Gligoric (2014). Based on experience from this particular period governments of the Czech and Slovak Republic prepared the concepts of funds drawing in each of the following programming periods. The aim of this article is to present the approaches of the Czech and Slovak public administration to the concept of implementation of EU cohesion policy for the programming period 2014 – 2020.

## **2 TOWARDS PROGRAMMING PERIOD OF COHESION POLICY OF THE EUROPEAN UNION**

In the shortened programming period 2004 - 2006 the government of the Czech Republic prepared the implementation of EU cohesion policy by means of five operational programmes, one of which was introduced as a joint Regional Operational Programme, other tools of this period included community initiatives and two single programming documents (Blažek 2003, Blažek and Vozáb 2006). The Czech Republic also had access to the Cohesion Fund and within the three objectives the Czech Republic could acquire development support up to EUR 2.6 billion (Viturka et al. 2009, Grebeníček 2012). In the same programming period 2004 - 2006 the Slovak government could also draw the funds from the policy of economic and social cohesion of the EU. The Slovak public administration prepared the following concept using these tools - 4 operational programmes, two single programming documents, Community Initiatives and as well as the Czech Republic Slovakia too had accession to the Cohesion Fund (Kraftová, 2008). Thus in the period 2004 – 2006 Slovakia could draw up to EUR 1.05 billion for development support of its territory.

The following programming period for the years 2007 - 2013 brought so far unprecedented opportunity for the both countries to obtain European support for the implementation of projects in their territories. In the Czech Republic the public administration prepared to implement cohesion policy of the European Union within all three available objectives. Within the Convergence objective seven new regional operational programmes were prepared and the implementation ensured by a completely new public authority - the regional councils, thus reflecting the fact that the competitiveness and disparities is question of more administrative levels within a national state (Bachtler et al. 2007, Ivanová 2013). Eight more thematic operational programmes were prepared to be implemented in the entire territory of the Czech Republic, excluding the capital city of Prague, this again within the Convergence objective. For the objective Regional Competitiveness and Employment two operational programmes were prepared and for the third objective, European territorial cooperation, nine operational programmes existed. The total amount available to the Czech Republic in Structural Funds and the Cohesion Fund for period 2007 - 2013 amounted to 26.2 billion Eur, a significant amount which somewhat cushioned the negative external effects (Clowes and Bilan 2014). The Slovak Republic implemented cohesion policy in this period during the same objectives as the Czech Republic. The Slovak government elected to prepare 11 operational programmes financed by the Structural Funds and the Cohesion Fund, with a total financial allocation of 11.4 billion Eur (Charvát et al., 2013). This programming period constituted a major challenge for the governments of both countries. On the one hand there was the responsibility of preparing a sufficient absorption capacity of the entities within their territories in order to make maximum use of the European funds, on the other hand both governments had to prepare adequate control mechanisms to support truly beneficial projects,

as well as ensure adequate legal environment for the entire mechanism of drawing EU funds (Ferry and McMaster 2005, Cartwright and Batory 2012). How then was the conceptual preparation of public administration institutions of both countries reflected in the actual implementation of EU cohesion policy?

### **3 CZECH AND SLOVAK REPUBLIC - EMPIRICAL EVALUATION OF THE PROGRAMMING PERIOD 2007-2013**

Assessment of the situation in the Czech Republic is based on an analysis of 32 800 projects, which were recorded in the relevant sources as of March 2013 and the total amount allocated to these projects amounted to CZK 355.6 billion. The first step of the analysis focused on the evaluation of the financial allocation of the EU funds within individual types of supported regions as determined by the location of project implementation, where the aggregated values obtained were recalculated per 1 inhabitant of the territory. Table 1 presents the main results in this regard:

- Regions with concentrated state support reported slightly lower allocation of financial resources of the European Union per 1 inhabitant than is the case in the regions not included in this category.
- Within the sub-types of regions with concentrated state support the lowest financial allocation of the European Union per 1 inhabitant is recorded in the economically weak regions, financial allocations for the other two types of regions with concentrated state support is higher.

Figure 1, completed via ESRI ArcGIS software, complements the above mentioned conclusions with the observation that there are also differences between regions with concentrated state support. This way regions with concentrated state support can be identified in which the financial allocation of EU funds exceeds the national average of CZK 43 954 per 1 inhabitant. Most of these regions, however, do not reach this value. So far, these claims are consistent with the findings published by Hájek et al. (2012), which were formulated using a similar methodology applied to a lower number of projects (as of April 2011).

Tab. 1 – Allocation of EU funding per 1 inhabitant by the type of supported region; evaluation by location of project implementation site (as of March 2013). Source: Authors' calculations based on data by Centre for Regional Development of the CR, Ministry of Regional Development and Czech Statistical Office

Type of region	Financial allocation (CZK)
Regions with concentrated state support	46 933
- structurally affected	48 693
- economically weak	39 699
- affected by high unemployment	55 579
Other regions	49 345

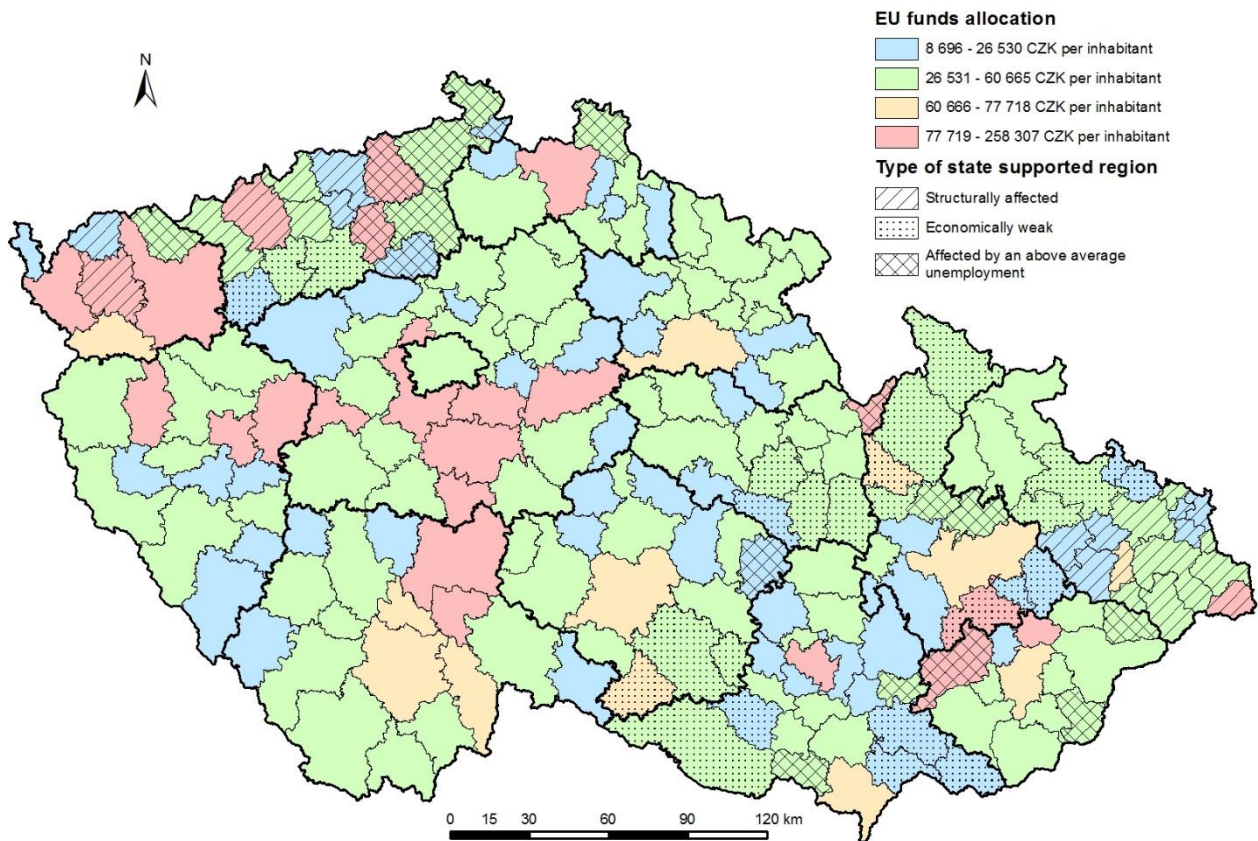

Fig. 1 – EU funding per 1 inhabitant in municipalities with extended scope of powers across supported region type; evaluation by location of project implementation site (as of March 2013). Source: Authors', based on Regional Information Service data, Czech Statistical Office for number of inhabitants

Tables 2 and 3 show the results of evaluation of the structure of the EU funds financial allocation within individual types of the state supported regions with regards to the institutional sector (table 2) and with regards to the thematic focus of the projects (table 3). The following facts may be derived from the tables:

- Public institutions, primarily the central public institutions, are the main recipient of EU funds. The structure of the financial allocation of these funds as dispersed among the different types of state supported regions is similar. The most significant difference can be seen in the case of a higher share of local government on financial allocation of EU funds in the economically weak regions at the expense of lower share of the central government.
- In terms of thematic focus of the projects some differences can be observed in the structure of the financial allocation of EU funds between structurally affected regions on one side and the other regions on the other. Thus, the first type of regions is characterized by a higher share of financial allocations in transport infrastructure and services topic, while the second type of regions have higher proportion of financial allocation in the research, development, innovation or development of human resources.

Tab. 2 – Financial allocation in the Czech Republic, structure by regional type and institutional sector; evaluation by location of project implementation site (as of March 2013). Source: Authors' calculations based on data by Centre for Regional Development of the CR and Ministry of Regional Development

Institutional sector	Regions with concentrated state support				Other regions
	Total	1*	2**	3***	
Local government	31.7 %	29.6 %	37.5 %	28.5 %	27.4 %
Non-profit non-government	3.9 %	4.8 %	2.6 %	3.7 %	3.5 %
Private	21.5 %	20.5 %	23.6 %	20.7 %	17.1 %
Central government	42.9 %	45.1 %	36.3 %	47.1 %	51.9 %

\* 1 – Structurally affected regions

\*\* 2 – Economically weak regions

\*\*\* 3 – Regions affected by high unemployment

Tab. 3 – Financial allocation in the Czech Republic, structure by regional type and thematic focus; evaluation by location of project implementation site (as of March 2013). Source: Authors' calculations based on data by Centre for Regional Development of the CR and Ministry of Regional Development

Thematic focus of projects	Regions with concentrated state support				Other regions
	Total	1*	2**	3***	
Transport infrastructure and services	40.6 %	39.5 %	39.5 %	43.8 %	30.2 %
Effective public administration and services	15.0 %	15.3 %	13.3 %	16.7 %	13.9 %
Environmental infrastructure and human resources	10.0 %	7.1 %	15.0 %	9.2 %	9.2 %
Human resources development	7.0 %	7.2 %	7.5 %	5.8 %	10.2 %
Enterprise environment development	8.9 %	9.4 %	7.8 %	9.1 %	10.0 %
Social infrastructure and social development aspects	5.3 %	5.6 %	4.9 %	5.3 %	5.5 %
Research. development and innovation	13.3 %	15.9 %	12.1 %	10.0 %	20.9 %

The Slovak Republic evaluation is based on the analysis of a total of 7,500 projects which were recorded in the relevant sources as of March 2013 and that the total with total value of the projects amounting to EUR 912 million. The first step of the analysis, as in the case of the Czech Republic, focused on the evaluation of the financial allocation of EU funds within individual types of state supported regions, depending on the site of the project implementation. The aggregated values obtained were recalculated per 1 inhabitant of the territory. Table 6 presents the main results in this regard:

- The growth poles of Slovakia have higher financial allocations from the European Union funds per 1 inhabitant than the municipalities not included in the growth poles category.

- As for the sub-types of the growth poles larger financial allocation per inhabitant is concentrated in the innovative growth poles, the cohesion growth poles are characterized by smaller allocation.

Figure 2, completed via ESRI ArcGIS software, adds to the above mentioned conclusion with the observation that there are also differences between the growth poles. As present in the case of the Czech Republic, there are municipalities not classified as growth poles, which have relatively high financial allocations from the European Union per 1 inhabitant.

Tab. 4 – Financial allocation of EU funds in Slovakia, structure by regional type; evaluation by location of project implementation site (as of March 2013). Source: Authors’ calculations based on data by Central register of contracts maintained by Government Office of the Slovak Republic, Central Coordination Authority and Statistical Office of the Slovak Republic for number of inhabitants

Municipality type	Financial allocation (€)
Growth poles	1 376
- innovation growth poles	1 440
- cohesion growth poles	1 287
Other municipalities	966

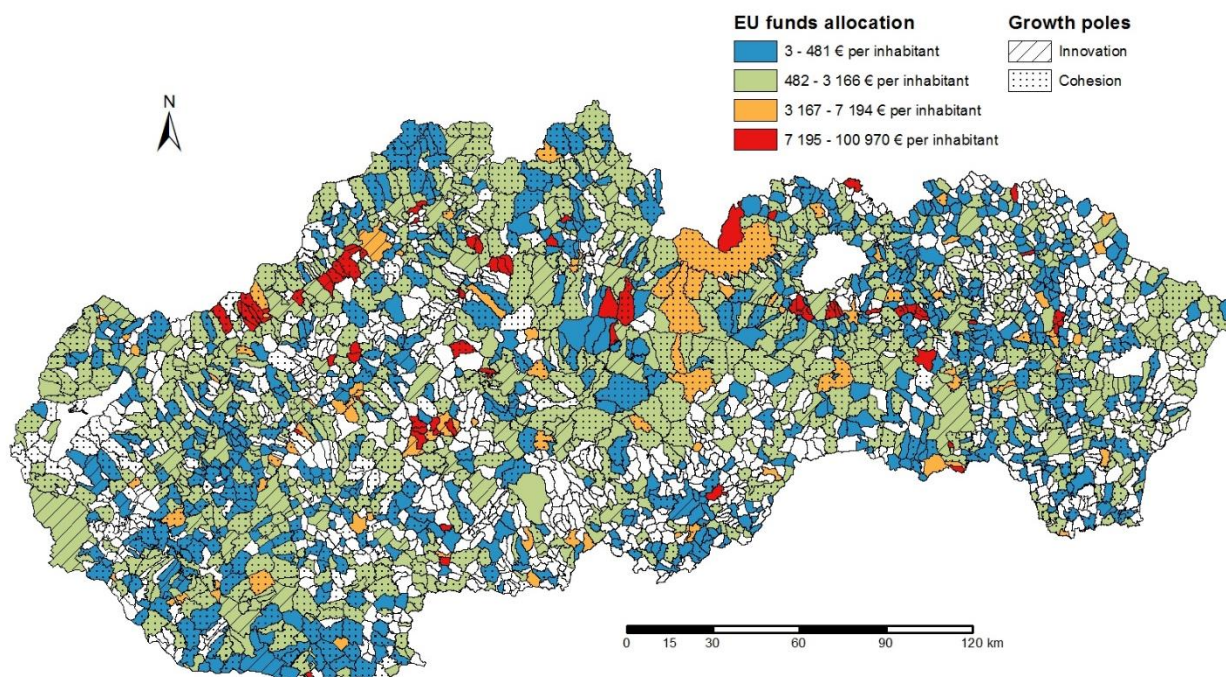

Fig. 2 – EU funding per 1 inhabitant in municipalities across growth pole type; evaluation by location of project implementation site (as of March 2013). Source: Authors’ based on data by Central register of contracts maintained by Government Office of the Slovak Republic, Central Coordination Authority and Statistical Office of the Slovak Republic for number of inhabitants

Tables 5 and 6 represent, as in the case of the Czech Republic, the results of the evaluation of the EU financial allocation structure within individual types of supported regions with regards to the institutional sector (table 5) and with regards to the thematic focus of the projects (table 6). Following conclusions might be drawn based on this data:

- Evaluation by institutional sector of the beneficiary provides similar results as in the case of the Czech Republic and in Slovakia. Thus, even in the case of Slovakia are public institutions, primarily the central public institutions, the main recipients of EU funds. Also, the structure of the financial allocation of these funds by institutional sector of the beneficiary and in relation to different types of assisted regions is similar. As in the case of the Czech Republic may be the most striking difference seen in a higher proportion of local government financial allocation of EU funds in the cohesive growth poles as economically weak regions of Slovakia.
- Evaluation of the structure of the financial allocation of EU funds according to the thematic focus of the projects shows differences between the various types of assisted regions of Slovakia. The main difference can be seen between growth poles on one side and municipalities outside the growth poles on the other. In the case of the second type of cases significantly higher share in the structure of the financial allocation of EU funds for thematic focus in the area of transport and environmental infrastructure. This is in a slightly lesser extent, also in case of cohesive growth poles. Conversely innovative growth poles show a significantly higher proportion particular topic research, development and innovation, but also the issue of social infrastructure and development aspects.

Tab. 5 – Financial allocation in Slovakia, structure by regional type and institutional sector; evaluation by location of project implementation site (as of March 2013). Enterprise environment development	6.0 %	5.7 %	6.7 %	3.6 %
Social infrastructure and social development aspects	10.2 %	14.0 %	4.3 %	2.0 %
Research, development and innovation	15.3 %	22.0 %	4.8 %	2.3 %

#### **4 COMPARISON OF THE CZECH AND SLOVAK PUBLIC ADMINISTRATION APPROACH TO THE CONCEPT OF EU COHESION POLICY IMPLEMENTATION FOR THE PROGRAMMING PERIOD 2014 – 2020**

Czech and Slovak public administration already have extensive experience in preparing for implementation of an economic and social cohesion policy programming period of the European Union. Government of the Czech and Slovak Republic used these experiences in the preparation of the programming period for the years 2014 - 2020. In terms of comparison of the architectural concepts of this EU policy implementation into national frameworks the Czech Republic may use an amount of up to EUR 23.9 billion and the Slovak Republic was allocated financial framework of EUR 15.5 billion for the 2014 – 2020 period.

Czech administration prepared following operational programmes in order to obtain monetary support from the European Structural and Investment Funds: Operational Programme Transport with an allocation of EUR 4.7 billion, Integrated Regional Operational Programme with an allocation of EUR 4.6 billion, Operational Programme Enterprise and Innovation for Competitiveness was allocated EUR 4.3 billion, Operational Programme Research Development, and Education with an allocation of EUR 2.8 billion, Operational Programme Environment with an allocation of EUR 2.6 billion, Rural Development Programme with an allocation of EUR 2.3 billion, Employment Operational Programme with an allocation of EUR 2.1 billion, Operational Programme Technical Assistance with an allocation of EUR 0.22 billion, Operational Programme Prague - A Pole of Growth with an allocation of EUR 0.2 billion, and Operational Programme Fishery with an allocation of EUR 0.03 billion. Other policy instruments were also prepared in the form of eight operational programmes of cross-border or international cooperation as well as ESPON 2020 and Interact III programmes (Ministry of Regional Development, 2014).

Slovak administration prepared following programmes for drawing from European structural and investment funds: Operational Programme Research and Innovation with an allocation of EUR 2.2 billion, Operational Programme Integrated Infrastructure with an allocation of EUR 4 billion, Operational Programme Human Resources with an allocation of EUR 2 billion, Operational Programme Environmental Quality with an allocation of EUR 3.1 billion, Integrated Regional Operational Programme with an allocation of EUR 1.8 billion, Operational Program Effective Public Administration with an allocation of EUR 0.27 billion, Operational Programme Technical Assistance with allocations EUR 0.16 billion, Rural Development Programme with an allocation of EUR 1.5 billion, and Operational Programme Fishery with an allocation of EUR 0.1 billion (Slovakia, 2014). Among other instruments seven operational programmes of cross-border or international cooperation were readied as wells as Interreg, ESPON, Interact and Urbact programmes.

In this period both countries will deal with notable challenges in terms of meeting the newly required conditionalities, setting their own objective with strengthened responsibility for meeting them (Mendez, 2013), promoting economic growth in the aftermath of the economic crisis and subsequently confront the decline in wealth as reflected in viability of the companies and number of personal bankruptcies (Paseková, 2013). The countries will also have to introduce new way of using the ESIF via recoverable monetary assistance further increasing the pressure on banking sector, its security and customer treatment (Belás et al. 2013a and Belás et al. 2013b).

## **5 CONCLUSION**

Institutions of public administration in the Czech and Slovak Republic already have experience with several programming periods of the European Union cohesion policy therefore this article focused on the challenge which was presented by preparing the strategic architecture for a new programming period. In spite of the above mentioned experience the public administration at both sides of the border recorded repeated difficulties in the preparation of the programming period 2014 - 2020 and failed to ensure timely start of fund drawing. In the case of the Czech Republic the issues is further exacerbated by issues of public procurement and public service (see e.g. Jurčík, 2014). During the current period, the concept of concentration was strengthened in both countries, which may lead to increased effectiveness and efficiency of obtaining monetary resources through the defined operational programmes and thus to an increase in the overall absorption capacity of both the compared countries. Both member states belong among those ranking highest when comparing the allocation per capita. They owe this enviable position to their relatively high allocations of EUR 23.9 billion in the case of the Czech Republic and EUR 15.5 billion in case of Slovakia. The use of this funding in the Czech Republic can be summarized as strongly focused on public sector with relatively loose spatial targeting in spite of declaration of support of economically lagging regions. Moreover the differences between economically lagging regions and other regions are more visible in terms of thematic structure of the projects. In this regard the economically lagging regions are characteristic by implementing projects of lower added value concerning basic infrastructure while the economically better off region focus more prevalently on research, human resources and other types of projects with larger added value. Slovakia suffers from even more pronounced differences among the economically advanced growth poles and other economically weaker regions which are likewise characteristic by infrastructure related projects. The focus of public sector remains central in Slovakia as well as in the Czech Republic. To conclude this comparison, both states implement the EU cohesion policy of the current programming period in relatively similar

context and it will be rather interesting to see, similarly as in Chapter 3 of this text, the successful implementation of this public policy in the Czech and Slovak Republic.

### **Acknowledgement**

Authors are thankful to the Internal Grant Agency of FaME TBU No. IGA/FaME/2015/026 “Návrh modelu vzniku klastrové organizace v oblasti zemědělství v podmínkách České republiky a v oblasti designu na Slovensku” for financial support to carry out this research.

The authors are thankful to the Operational Programme Education for Competitiveness co-funded by the European Social Fund (ESF) and national budget of the Czech Republic for the grant No. CZ.1.07/2.3.00/20.0147 - “Human Resources Development in the Field of Measurement and Management of Companies, Clusters and Regions Performance”, which provided financial support for this research.

## **RESEARCH AND DEVELOPMENT EXPENDITURE ASSESSMENT BASED ON SELECTED INDICATORS IN THE EU COUNTRIES**

*Martina Halásková, Renáta Halásková*

### **Abstract**

The paper evaluates and compares financing of Research and Development (R&D) in EU countries. Close attention is paid to the comparison of total expenditure on R&D (GERD) in EU (28) countries, including R&D expenditure based on sectors (the business enterprise sector, the government sector, the higher education sector, the private non-profit sector) in years 2004 and 2013. Results of the research provide a comparison of public expenditure on R&D in the government sector and the higher education sector in years 2004, 2009 and 2013 in EU countries (in %), and based on the R&D intensity (in % of GDP). Using the correlation analysis, further assessment of mutual relationship of total expenditure on R&D and selected R&D indicators (patents, number of publications, researchers, and GBAORD) is provided.

*Keywords: research and development, expenditure, assessment, indicators of R&D, EU countries*

JEL Classification: H59, O39

### **1 INTRODUCTION**

Research and development (R&D) play a key role in creating new knowledge, products and technological processes, which are a necessary prerequisite for a stable and sustainable economic growth within a society. R&D have become one of the central areas of national and international policies over recent years. Both EU initiatives and individual states have been paying their attention to conditions for research, development and innovations over recent decades. The level and intensity of research, development and innovations is closely connected with the economic development, the dynamics of economic development, and the structure of generating added value and employment. The strongest emphasis is put on improving the conditions of financing research, development and innovations in EU countries. Public direct and indirect support of R&D is for developed countries one of the ways of contributing to an increased competitiveness of their economies in the long-term perspective (European Commission, 2010). The policy of research and development is a standard part of the integrated system of national policies related to main areas of functioning of a society in most developed countries. This mainly concerns interconnectedness of the R&D policy with the policy of education, innovation, employment, information and the policy of industry and business. The European Research Area (ERA) concentrates its European resources associated with science, research and innovations, in order for an enhanced coordination of these activities, at the level of both member states and the EU. At the European level research faces numerous inefficiencies. These are scattered activities, isolated national research systems, low financing from public and private resources, and low investments in knowledge development. Usage of financial resources in terms of the ERA enables comparing results, conducting multidisciplinary studies, and gaining access to sources and services of “*centre excellence*” and to the most advanced technology (Delanghe, Muldur & Soete, 2009). The development of knowledge economy, trends in R&D, and relations between R&D expenditure and other indicators in EU countries are supplied by research and studies already carried out (Bojnec & Ferto, 2014; Krčál, 2014; OECD, 2014a; UNESCO-UIS, 2014).

## **2 THEORETICAL FRAMEWORK OF RESEARCH AND DEVELOPMENT**

Science, research, development and innovations are one of the numerous sources of economic growth and social welfare. From the viewpoint of macro-economy, the areas of research and development belong to the category of intensive (qualitative) sources of economic growth, i.e. they enable the increase in and improvement of the productivity based on the factors of production (European Commission, 2010). Currently, what mainly dominates the development of economies and societies is knowledge connected with research and development outputs. Significant economic indicators, such as economic growth, unemployment rate, or company competitiveness, are, according to Lelek (2014); Majerová (2014); OECD (2014a), actually dependent, to a marked extent, upon the outcomes of research and development. What is connected with the mutual relationship between inputs and outputs is the term “efficiency”, which can generally be defined as “attaining maximum results from a given volume of resources used in doing an activity (UNESCO-UIS, 2014).

Science, research and development have a significant place in areas of national economies and the public sector. Based on the demands of the public sector, science and research are placed into the category of knowledge and information. R&D focus on society as a whole, their role lies in satisfying the need for knowledge and using new information, in increasing welfare, and in boosting the standards of living (European Commission, 2010; Wildmannová, 2013). From another viewpoint, science, research and development, according to Stiglitz (1988), can be placed into the area of services. R&D is part of economic activity classification (NACE), where they belong to the section of Professional, scientific and technical activity. Elementary R&D are included in the COFOG classification (Classification of the functions of the government), being one item from the category of General public services. Related R&D are included in other items of COFOG classification (e.g. Social protection, Health, Education) (Szarowská, 2013).

An important conditions for fulfilling the Europe 2020 strategy in the area of R&D are financial capabilities of the individual countries (European Commission, 2010). The largest and most significant program that provides financing for science, research, development and innovations at the European level is for the period 2014–2020 the Horizon program (H2020). It is a framework program for research and innovations, following up on programs for research, which the EU has been announcing since as early as 1980. What is supported is the connection to the structural funds and other EU programs. In the formulation stage of the H2020 program, objectives were defined which are to be reached and which will serve as indicators of the program evaluation (i.e. enhanced competitiveness, new jobs, increased employment) (European Commission, 2010).

International comparison mostly measures total expenditure on R&D (GERD) towards GDP. This financial relation is called “research and development intensity” and belongs to the group of elementary structural indicators evaluating the progress of Lisbon-treaty objective-fulfilments in individual EU countries (European Commission, 2010; Halásková, 2011; OECD, 2014a). Gross domestic expenditure on research and development (GERD) includes all R&D activities performed within the territory, whatever the origin of funding. This sector presents various indicators that provide information on GERD as a whole, GERD performance structure and GERD financing structure. The total expenditure on R&D (GERD) includes expenditure on doing research and development in four sectors according UNESCO-UIS (2014), namely:

- **Government sector** – Government intramural expenditures on research and development (GOVERD) include all government R&D activities by R&D performance structure and financing structure. The Government sector includes expenditures on the workplace of the

Academy of Science, research facilities, libraries, archives, museums, and other institutions.

- **Higher education sector** – Higher education expenditures on research and development (HERD) include R&D activities performed by the higher education sector. This sector includes public and state universities, teaching hospitals, and private universities, and expenditures on research and development associated with these institutions.
- **Business enterprise sector** – Business enterprise expenditures on research and development (BERD) includes all R&D activities performed in Québec by enterprises. This sector provides information on R&D performance, R&D financing structure, distribution of enterprises conducting R&D, R&D activities in the information and communication technology (ICT) sector, industrial R&D tax support, R&D personnel and R&D activities by administrative region.

In addition, another sector involved is the **Private non-profit sector**, which comprises but a small part of conducted R&D and associated expenditure (see Table 2).

### **3 OBJECTIVE AND METHODS**

Based on theoretical-empirical approach, the paper aims to compare and evaluate sources of financing R&D in EU countries, focusing on selected R&D indicators. More closely, it focuses on changes in total expenditure on R&D in EU countries, including sectors conducting them, comparison of expenditure in the government sector and the higher education sector in EU countries in years 2004, 2009, and 2013, and on an evaluation of mutual relations of total expenditure on R&D and selected indicators of R&D.

Key methods of scientific research are those based on analysis, comparison and abstraction in the creation of the theoretical-methodological frame for the solution; methods of causal analysis and comparison when solving the defined research question in the application part, and methods of synthesis and partial induction when concluding the outcomes. Gross Domestic Expenditure on R&D (GERD) in EU countries including expenditure for individual sectors (Expenditure on R&D in the Business Enterprise Sector (BERD), Government Intramural Expenditure on R&D (GOVERD), Expenditure on R&D in the Higher Education Sector (HERD)) were compared in years 2004, 2013. Public expenditure on R&D (government and higher-education sector) in EU countries in years 2004, 2009, 2013 are compared (as % and as % of GDP).

The selected group comprises 28 EU countries (Belgium-BE, Bulgaria-BG, Czech Republic-CZ, Denmark-DK, Germany-DE, Estonia-EE, Ireland-IE, Greece-EL, Spain-ES, France-FR, Croatia-HR, Italy-IT, Cyprus-CY, Latvia-LV, Lithuania-LT, Luxembourg-LU, Hungary-HU, Malta-MT, Netherlands-NL, Austria-AT, Poland-PL, Portugal-PT, Romania-RO, Slovenia-SI, Slovakia-SK, Finland-FI, Sweden-SE, United Kingdom-UK). A secondary collection of data from available Eurostat statistics was carried out through the constructive method, and its processing and interpretation through statistical methods with the emphasis placed on correlation analysis. For the correlation analysis, statistical data from 2012 was used due to the fact that the data from 2013 was not available for all observed indicators in EU countries. Selected indicators (researchers, patents and number of publications and GBAORD) were used to evaluate the total expenditure of efficiency in R&D in EU28 countries in 2012 (Tab. 1).

What is being statistically tested is the research matter of the existence of the relations between the extent of total expenditure on R&D, and between the selected indicators (patent applications to the EPO applications per million inhabitants, total researchers head count, number of

publications in R&D per thousand inhabitants, government budget appropriations or outlays for R&D (GBAORD) as a % of total general government expenditure) in EU countries in the year 2012 by means of correlation analysis.

Tab. 1 – Selected R&D indicators in EU countries in 2012. Source: Authors according to Eurostat (2015)

From the perspective of standardized method of statistical testing of the dependence of variables (e.g. Spearman's rank correlation coefficient, where no linearity of the expected relationship or the common distribution of two variables can be supposed, Kendall's coefficient of concordance, based on data related to metric or ordinary evaluation of  $n$  objects ( $i = 1, 2, \dots, n$ ) according to two criteria X and Y) (Lynch, 2013) and the character of available data, the method using the Pearson's correlation coefficient appears the most appropriate.

The Pearson correlation coefficient determines the strength of the dependence between the observed variables. It shows the level of closeness of linear dependence. The estimate of a pair correlation coefficient is defined as the estimate of covariance  $x$  and  $y$  divided by the multiplication of estimates of their standard deviations, i.e.

$$r_{yx} = \frac{\text{COV}_{xy}}{s_x s_y} \quad (1)$$

where  $\text{COV}_{xy}$  is the covariance between  $x$  and  $y$  a can be calculated as the average of multiplication of deviations, i.e. it is a "common" measure of variability (covariance) for two features ( $x$  and  $y$ ). The equation is based upon covariance, which is the level of mixed variability of variables  $x$  and  $y$ .

$$\text{cov}_{xy} = \frac{1}{n} \sum_{i=1}^n (x_i - \bar{x})(y_i - \bar{y}) = \overline{xy} - \bar{x} \cdot \bar{y} \quad (2)$$

The coefficient of pair correlation (Pearson correlation coefficient) uses the values ranging

from <-one, +one>, while the more the value approaches -one, the closer the correlation (direct linear correlation in case of positive values, indirect in case of negative ones); the more it approaches zero, the weaker the correlation is. Correlation coefficients provide, on both sides, the dependence between  $x$  and  $y$  (Lynch, 2013; Harlow, 2010). The calculations in the following part are the output of the SPSS Statistics 21.0 software.

## 4 RESULTS

### 4.1. Comparison of total R&D expenditure in EU countries and R&D expenditure based on sectors

In 2013, the EU28 Member States spent almost €275 billion on Research & Development (R&D). The R&D intensity, i.e. R&D expenditure as a percentage of GDP, stood at 2.02% in the EU28 in 2013, compared with 1.76% in 2004. In 2013, the highest R&D intensities were recorded in Finland (3.32%), Sweden (3.21%) and Denmark (3.05%), all above 3% of GDP, followed by Germany (2.94%) and Austria (2.81%). At the opposite end of the scale, ten Member States recorded an R&D intensity below 1% of GDP: Romania (0.39%), Cyprus (0.48%), Latvia (0.60%), Bulgaria (0.65%), Greece (0.78%), Croatia (0.81%), Slovakia (0.83%), Malta (0.85%), Poland (0.87%) and Lithuania (0.95%). Compared with 2004, R&D intensity increased in twenty-two Member States, decreased in Croatia (from 1.03% in 2004 to 0.81% in 2013), Luxembourg (from 1.63% to 1.16%) and Sweden (from 3.39% to 3.21%), and remained almost stable in Romania, Finland and the United Kingdom (Eurostat, 2015).

Total expenditure on R&D in the EU28 Member States as % of GDP in years 2004 and 2013 is provided in Figure 1. A more detailed comparison of R&D expenditure in years 2004 and 2013 by sector performance is provided in Table 2. The business enterprise sector continued to be the main sector in which R&D expenditure was performed accounting for 64% of total R&D conducted in 2013, followed by the higher education sector (23%), the government sector (12%) and the private non-profit sector (1%).

Fig. 1 – Total Research and development expenditure in the EU28 Member States (as % of GDP). Source: Authors according to Eurostat (2015)

The main sector in which R&D was performed in 2013 was the business enterprise sector in all

Member States, except Greece, Cyprus, Latvia, Lithuania (where the higher education sector was the dominant performing sector) and Romania (where almost half of the R&D expenditure was conducted within the government sector). The highest shares of R&D expenditure performed in the business sector were observed in Slovenia (77%), Ireland (72% in 2012), Belgium, Hungary, Austria and Finland (all 69%), Germany and Sweden (both 68%) and Denmark, France and the United Kingdom (all 65%). Compared with 2004, the share of R&D conducted in the business enterprise sector increased in fifteen Member States, decreased in twelve, while it remained stable in Belgium and within the government sector in Romania and the higher education sector in Cyprus and Lithuania. For the government sector, the highest share was by far registered in Romania (49%), followed by Bulgaria (30%), Latvia (29%), Greece and Poland (both 27%) and Croatia (26%). The highest shares of R&D conducted within the higher education sector were recorded in Cyprus (57%), Lithuania (55%), Latvia (43%) and Estonia (42%) (Table 2).

----------------	----	----	----	---	----	----	---	---

Note: (– not applicable, 0 = less than 0.5%)

Apart from total R&D expenditure and expenditure by sectors, what also can be observed are other key indicators related to total expenditure. One of these, related to R&D financing, is Government Budget Appropriations or Outlays for R&D (GBAORD) as a % of total general government expenditure (Eurostat, 2015).

Fig. 2 – GBAORD in EU countries in year 2012 (as a % of total general government expenditure). Source: Authors according to Eurostat (2015)

The results of comparison (GBAORD) in EU countries in 2012 are presented in Figure 2, which shows that the highest ratio of Government Budget Appropriations or Outlays for R&D (GBAORD) to total general government expenditure in 2012 was in Estonia and Germany, as opposed to Latvia and Romania, with the lowest GBAORD from all EU countries.

#### 4.2. R&D expenditure comparison in government and higher education sector in EU countries

This part deals with the comparison of public expenditure on R&D, i.e. expenditure on R&D in the government sector (GOVERD) and higher education sector (HERD). In 2013, expenditure on R&D carried out in the government and higher education sectors reach 96.8 billion Euros in the EU28, thus by 0.6 billion Euros more compared with the previous year. The Czech Republic belongs to the countries with a higher representation of public resources in R&D financing. In 2013, public resources accounted for 45% of total R&D expenditure (GERD), which is approximately 10% above the average of the EU28, where public resources accounted for approximately 35% of total R&D expenditure in 2013.

R&D in the government sector and higher education sector play an important role (accounting for no less than 40%) in relation to total R&D expenditure, mainly in countries entering the EU in 2004 and later (except for Hungary, Estonia, and Slovenia), but also in Greece, Spain, Portugal, Italy, and the Netherlands. The strongest position of higher education sector in terms of the public R&D in EU countries is present in Denmark, Malta, Ireland, and Sweden. By contrast, in most EU countries (entering the EU in 2004 or later, with the exception of the Baltic states), the government sector plays a more dominant role, mainly due to its strong position of institutions of the Academy of Science type (e.g. in Poland or Hungary), or owing to low expenditure on R&D in higher education sector (Bulgaria, Romania). Among countries with a balanced ratio of higher education sector and government sector belong France, with notable expenditure on defence R&D, and Germany, with a dominant position of four research institutes. Total expenditure on R&D of government and higher education sector in EU countries (in %) is provided in Figure 3.

However, we get a completely different view of the significance of government and higher

education sector in the R&D area from the above mentioned order of EU countries, compiled based on the representation of these sectors in GERD, should the expenditure in these sectors be expressed as % of GDP in each country. In 2013, expenditure allocated to the public R&D in EU countries accounted for 0.72% of GDP (0.64% in 2004). Public R&D reaches the highest representation in GDP, around 1%, in Finland, Sweden, Denmark, and the Netherlands, as opposed to the lowest representation of R&D in GDP, less than 0.5%, which was observed in most member states entering the EU in 2004 and later (with the exception of Estonia, Slovenia, and the Czech Republic), despite a notable representation of public R&D in total R&D expenditure.

Fig. 3. – Total R&D expenditure (%) in the government sector (GOVERD) and higher education sector (HERD) in 2013. Source: Authors' calculation according to Eurostat (2015)

Total R&D intensity in government sector (GOVERD) and higher education sector (HERD) (in % of GDP) in 2004, 2009, and 2013 is presented in Figure 4.

Fig. 4 – R&D intensity in the government and higher education sector (% of GDP). Source: Authors according to Eurostat (2015)

R&D intensity solely in government sector is provided in Figure 5. Preceded by Germany, Slovenia, and Finland, the Czech Republic is a country with the highest expenditure on R&D in government sector (GOVERD) relative to GDP. In the Czech Republic, R&D expenditure in government sector in relation to GDP comprises a larger part by one quarter than the EU28 average in 2013, which reached (as well as in 2000) 0.25%. Compared with the EU28 average

in 2004 and 2009, that is a small decline (0.24%), and a small increase (0.26%), respectively.

In 2013, higher education R&D reached the highest values in % of GDP in Scandinavian countries, similarly to other indicators, varying from 0.71% in Finland, to 0.97% in Denmark from EU28. As a large number of EU member states, the Czech Republic had long been lagging behind the EU average (0.47%), but in recent years it was approaching it quickly. In 2013, with 0.52% of GDP, it even surpassed the EU average (see Figure 6).

Fig. 5 – R&D intensity in EU countries in the government sector (% of GDP). Source: Authors according to Eurostat (2015)

In absolute figures, all EU28 countries allocated 63.4 billion Euros to R&D conducted at universities, which is by 30 billion Euros more than in government sector. University institutions in Germany, France, and the United Kingdom benefited from most of these resources. The Czech Republic accounted for 790 million Euros. 33.4 billion Euros was spent by government sector on conducted R&D in the EU in 2013, which is by 0.4 billion Euros more than in the previous year. Germany accounted for more than 1/3, and France for 1/5 of this sum. The Czech Republic accounted for 0.5 billion Euros, which is far the most out of all EU countries joining the EU in 2004 or later (with the exception of Poland).

Fig. 6 – R&D intensity in EU countries in the higher sector (% of GDP). Source: Authors according to Eurostat (2015)

#### 4.3. Mutual relation of total expenditure on R&D and selected indicators using correlation analysis

Correlation coefficient ( $r$ ) and coefficient of determination ( $r^2$ ) were calculated to evaluate the mutual relation between R&D inputs and outputs. Correlation between total expenditure on R&D and selected indicators of R&D in EU countries was observed in 2012. For more specific information about the output of Pearson correlation coefficient and coefficient of determination, see Table 3. Results of correlation analysis between total R&D expenditure and selected R&D indicators in 2012 are presented in Figures 7, 8, 9, 10.

Tab. 3 – Pearson correlation coefficient and coefficient of determination, total R&D expenditure (GERD) and selected indicators. Source: own calculation

Mutual relations of total R&D expenditure and selected indicators	Pearson correlation coefficient ( $r$ )	Coefficient of determination ( $r^2$ )
Total R&D expenditure (% of GDP) and patent applications to the EPO applications per million inhabitants	0.865	0.749
Total R&D expenditure (% of GDP) and the number of publications in R&D per 1.000 inhabitants	0.800	0.640
Total R&D expenditure (% of GDP) and total researchers (head count)	0.310	0.096
Total R&D expenditure (% of GDP) and GBAORD as a % of total general government expenditure	0.682	0.466

A strong correlation between total R&D expenditure as % of GDP and Patent applications to the EPO applications per million inhabitants was proven in EU countries. This shows that Pearson correlation coefficient is 0.865 ( $p < 0.01$ ), and coefficient of determination is 0.749, i.e. 75%. The coefficient of determination results in the fact that the dispersion of the share of total R&D expenditure as % of GDP is from 75% explained by the dispersion of Patents applications to the EPO applications per million inhabitants, and from 25% is this relation influenced by other factors. A more noticeable dispersion is observed in Scandinavian countries, Germany and Austria (see Figure 7). Another strong correlation was proved between total R&D expenditure as % of GDP and the amount of publications in R&D per thousand inhabitants. This relation shows that Pearson correlation coefficient is 0.800 ( $p < 0.01$ ) and the coefficient of determination is 0.640, i.e. 64%. The coefficient of determination results in the fact that the dispersion of the share of total R&D expenditure as % of GDP is from 64% explained by the dispersion of the number of publications in R&D per 1,000 inhabitants, and from 36% is this relation influenced by other factors (Figure 8).

The last relation observed was between total R&D expenditure as % of GDP, and GBAORD as % of total general government expenditure. This relation results in the fact that Pearson correlation coefficient is 0.682 ( $p < 0.01$ ), and the coefficient of determination is 0.466, i.e. 46%. The coefficient of determination results in the fact that the dispersion of the share of total R&D expenditure as % of GDP is from 46% explained by the dispersion of GBAORD as % of total general government expenditure, and from 54% is this relationship influenced by other factors. A more noticeable dispersion is again observed in Scandinavian countries, Germany, Austria, and Estonia (Figure 9). By contrast, a weak correlation in all EU countries was proved between total R&D expenditure as % of GDP, and total number of researchers (head count).

This results in the fact that Pearson correlation coefficient is 0.310 ( $p < 0.01$ ) and the coefficient of determination is 0.096, i.e. 9.6%. The coefficient of determination results in the fact that the dispersion of the share of total R&D expenditure as % of GDP is from only 9.6% explained by the dispersion of the total number of researchers (head count), and from 90.4% is this relation influenced by other factors (Figure 10).

## 5 DISCUSSION

Evaluation of the Europe 2020 strategy shows that without sufficient volume of financial resources, both from the government and the business enterprise sector, it is not possible to expect that R&D will deliver internationally competitive information, innovations and technologies that will provide for increased productivity, employment and economic competitiveness (European Commission, 2010). The research studies carried out show that total expenditure on R&D (GERD) is a significant indicator for comparison and evaluation of economic competitiveness (European Commission, 2010; Majerová, 2014; OECD, 2014a). As some authors state e.g. Delanghe, Muldur & Soete (2009); Halásková (2011) or Bojnec & Ferto, (2014), total expenditure on R&D are mostly compared to GDP for the sake of international comparison, expressing “the R&D expenditure intensity”. The R&D intensity, i.e. R&D expenditure as a percentage of GDP, stood at 2.02% in the EU28 in 2013, compared with 1.76% in 2004. According to the Eurostat (2015), OECD (2014b) this level remained, however, lower in the EU28 than in other major economies. R&D intensity was much higher in South Korea (4.04% in 2011) and Japan (3.38% in 2011) as well as, to a lesser extent, in the United States (2.81% in 2012), while in both China (1.98% in 2012) and Russia (1.11%) the R&D intensity was below that of the EU28.

In almost all observed countries, including the Czech Republic, the last decade has seen an enhancement of the role of higher education sector in the structure of public research. This can be explained by increasing demands for quality and extent of not only elementary but also applied research at universities, which is one of the assessment criteria for their financing. The research aimed to define the mutual relation between total expenditure on R&D in EU countries (inputs) and selected key R&D indicators (outputs). Results of correlation analysis confirmed an effective relation between total research and development expenditure and patent applications to the EPO applications per million inhabitants, and between total research and development expenditure and the number of publications in R&D per 1000 inhabitants. Who takes a different perspective in their research are, for instance, Lelek (2014), dealing with R&D indicators (human resource in knowledge economy), and Bojnec & Ferto (2014), studying expenditure on R&D in OECD countries. According to the OECD (2014a); Eurostat (2015), the key indicator of R&D, pertaining to financing, is Government Budget Appropriations or Outlays for R&D (GBAORD) as a % of total general government expenditure. This was also confirmed by the results of the correlation analysis between total expenditure on R&D and

GBAORD, where a strong correlation is present. As the OECD (2014a) states, the number of publications connected to researchers' FTE in R&D is an approximate indicator of research-activity efficiency. The Czech Republic is found slightly above the EU average, at the same level as large EU countries (France, Germany, the UK). In EU countries with a size similar to the Czech Republic, this definition of research sphere is by 50–100% higher. A weak correlation was observed between total R&D expenditure (% of GDP) and total number of researchers (head count). When evaluating R&D, what needs to be considered is not only the total volume of resources and development of a given country, but also their structure and sources of financing. To evaluate R&D inputs and outputs, key indicators have to be defined, serving as an adequate criterion. Other key R&D indicators are considered to be from the area of human resources, for instance the number of researchers, the share of women, university educated individuals, and indicators focused on R&D (e.g. the number of publications per 1000 inhabitants, academic publication quote-level by subjects [% of the global average], number of EPO patent applications per 1 million inhabitants). This fact is also supported by other studies dealing with R&D evaluation and financing in EU countries (Aristovnik, 2012, 2014; Cohen, Nelson & Walsh, 2002; Krčál, 2014; Kubák et al.; Lee, Park & Choi, 2009). In connection with the extensive issue of R&D financing in EU countries, a large number of questions remain open, which can inspire future research.

## **6 CONCLUSION**

An important prerequisite for fulfilling the Europe 2020 strategy in the area of R&D are financial capabilities of the individual countries. Statistical data of the OECD enables analysis and coordination of policies of R&D of both the member states, and the EU as a whole. International comparison most frequently balances total expenditure on R&D (GERD) to GDP. The highest level of total expenditure on R&D is observed in Scandinavian countries (Finland 3.3% GDP, Sweden 3.2% GDP, Denmark 3.0% GDP, Germany 2.9% GDP). By contrast, the lowest level of total expenditure on R&D is observed in Romania 0.39%, Cyprus 0.48%, and Bulgaria 0.65%. The outcome of the R&D comparison in EU countries proved that their structure plays a significant role. R&D expenditure by sector performance vary considerably across EU countries. The business enterprise sector continued to be the main sector in which R&D expenditure was performed, accounting for 64% of total R&D, conducted in 2013, followed by the higher education sector (23%), the government sector (12%) and the private non-profit sector (1%). The comparison of public expenditure on R&D, i.e. the government (GOVERD), and the higher-education sector (HERD), showed that the majority of EU28 countries allocate more resources to the latter sector. In public expenditure, this expenditure reaches as much as 80%, or even more, in many countries. The largest expenditure of the government sector is observed in Romania and Bulgaria, which are countries that have very small expenditure on R&D in higher-education sector. In the observed period, balanced expenditure in the government and the higher-education sector is observed in France and Germany. The research results, using correlation analysis, have confirmed an effective relation between total R&D expenditure and the selected key indicators related to the R&D results and financing. The research confirmed a relatively strong correlation between total R&D expenditure (GERD) (% of GDP) and patent applications to the EPO applications per million inhabitants, numbers of publications in R&D per 1000 inhabitants and Government Budget Appropriations or Outlays for R&D (GBAORD). By contrast, no positive relation was found between total R&D expenditure and human resource indicators, i.e. between total R&D expenditure and total number of researchers, nor between expenditure and researchers in the GOVERD and HERD sectors.

## **PUBLIC SECTOR EFFICIENCY ANALYSIS - ISSUES AND PERSPECTIVES**

*Hamerníková Bojka, Maaytová Alena*

### **Abstract**

The public sector efficiency analysis, its segments, and institutions are one of the instruments utilized to increase the quality of economic policy. Thus, the research focus on the methods of efficiency analysis and their application to problems is topical. The aim of this paper is to present the emerging trends in this field with regard to the prospect of a possible broader application of selected methods to the Czech Republic.

*Keywords: efficiency, public sector, analysis methods*

JEL Classification: H10, H11, D61

### **1 INTRODUCTION**

The public sector and its efficiency have long been one of the most discussed issues of economic theory and practice. The close interconnection of this issue with the field of public finance enhances its controversial nature with regard to the dynamics of public spending, the development of tax burden, and growth of deficit and public debt. With regard to the past, ongoing, or planned public finance reforms, the problems and prospects of the public sector development have been, in the most recent years, “subdued” by the imperative to face the consequences of the global financial crisis by all possible means (including fiscal). Finding the optimal mix of anti-crisis measures and an adequate scope of selected steps (on a transnational or national level) represented just another phase in the long-term discussion among theoreticians, politicians, and practitioners about the role of the state in the economy; this time in terms of globally interconnected world markets, transactions, and impacts.

Long-term problems of public sector efficiency and public finances, albeit “under the banner” of anti-crisis measures in economic policy have resurfaced. Within the public sector efficiency analysis, the public sector cannot be separated from public finances. The interconnection of economic analysis in these two fields is derived from their close interconnection in reality. An unpopular and a difficult-to-accept “head of a coin” - the tax burden on taxpayers - is a common denominator for both the public sector and public spending.

The public sector efficiency, its analysis, and potential, as well as the problems of applying different methods, are topical issues, even in the Czech Republic. Despite some increase in research and scientific studies, there is still a plenty of space for deepening its methodological, analytical, and comparative research. Hence the aim of this paper is to analyse the current state in the field of public sector efficiency research, both abroad and in the Czech Republic, and present some approaches and methods that have been less frequent in our environment.

## **2 PUBLIC SECTOR EFFICIENCY - THEORETICAL REFLEXION**

The public sector efficiency and its theoretical reflection constitute a relatively large area of economics research and are subject to a long-term discussion. There are several causes why such a discussion has been underway for so long, for example:

- Problems with the definition and determination of the scope of public sector as well as the subject of its efficiency analysis (1)
- Specific features of the public sector production compared to the private sector production and the ensuing difficulty associated with its definition, expression, and measurement (2)
- Problems with the selection of effective methods and appropriate indicators to express and measure the public sector efficiency and its segments (3)
- Diversity and specifics of individual segments (regions or sectors) of public sector and their outputs, and the ensuing difficulty associated with the expression and measurement of the total (cumulative) efficiency (4)
- Existence (or absence) of relevant and quality statistical data (5).

The stated causes are both theoretical and methodological/analytical in nature.

In foreign publications on public sector and public finance written by J. E. Stiglitz (1997), R. A. Musgrave and P. B. Musgrave (1994) or P. M. Jackson and C. V. Brown (1990), which can be considered classics today, public sector is defined by a state's basic fiscal functions: allocation, stabilization, and redistribution.

Attempts of local literature to define the nature of public sector have been made mainly in the 1990's: C. Lawsson, J. Nemeč (1992), B. Hamerníková (1996, 1997, 1998), K. Kubátová (1999, 2000), Y. Strecková (1997, 1998), I. Malý (1998), R. Duben (2001), F. Ochrana (2001), J. Rektorič (2002), and others.

Together, with many other economists, it may be argued that the public sector and its scope should be understood in the broader context and defined by applying a set of criteria, such as the functions it meets, entities deciding about the nature and extent of its activities, the nature of ownership, management and funding of its institutions.

Public sector can include not only institutions, but also public expenditure projects and programs, including their implementation. The existence and development of the so-called nongovernmental (non-profit) sector, which is functionally related to public sector, creates new opportunities for the expansion of public projects and programs. To perform its functions, the public sector needs to have a huge amount of assets and services at its disposal. It can either directly produce or purchase both of them from private sector through public procurement. The meaningful use of these assets and services is possible only if outsourcing of the production to private sector leads to savings in expenditures on the part of public sector. The existence of these savings is strongly dependent on the transparency of procurement processes, lack of corruption, and the nature of the goods in demand (Hamerníková, Maaytová et al., 2007).

A problematic definition of public sector leads to difficulties with selecting of relevant indicators to express and effective methods to measure its size and efficiency. In the following text, we will focus our attention on the public sector efficiency. The methodological issues constitute a big obstacle to obtaining valuable and presentable conclusions in all analyses of the public sector efficiency and public spending. One of the sub-problems (albeit not less important) is the issue of selecting appropriate indicators and relevant data.

What may be considered when assessing the public sector efficiency and its optimal size is whether it is justifiable to include certain products in the public sector, as well as allocative and productive efficiency.

Due to close ties of public sector and public finances, it is important for a deeper analysis of its efficiency to also point out problems with the efficiency of public spending, projects, and programs. In the budgetary sphere, the efficiency has, over time, been increasingly understood in unity with its three dimensions: i.e., as a multiple of efficiency, efficacy, and effectiveness.

Analysis of the public sector efficiency can be focused in different ways, for example, on:

- the efficiency of its institutions, the efficiency of its chosen segments, the public sector efficiency as a whole over several years, international comparison.

According to J. Bénard (1991), the methods of analysing the efficiency of public expenditure, projects and programs can be classified into mono-criteria methods and multi-criteria methods, in which it is difficult to determine the significance of one criterion over other criteria.. “The advantage of multi-criteria methods is that they cannot reduce non-economical criteria to economic criterion at the expense of sensitive and sometimes controversial operations” (Bénard, 1991). Regarding the existing methods, their techniques and procedures are described very well in foreign and domestic literature (Ochrana, 2004; Strecková, Malý, 1998; Wright, Nemeč, 2003). It is particularly important to assess these options properly, with respect to the analysed problems, including the role of a time factor; a fact that is highlighted by a number of authors (e.g., Allen, Tommasi, 2002).

### **3 SELECTED APPROACHES TO THE PUBLIC SECTOR EFFICIENCY ANALYSIS**

The difficulty determining the public sector efficiency, its segment, and institutions causes that inventors of new methods are increasing creative. Not only domestic, but also foreign economic research has, in recent years, brought many positive results in the application of new techniques, methods, and analysis techniques. The application of methods such as Data Envelopment Analysis (DEA) and the Free Disposable Hull (FDH) serves as an example of this innovative approach.

Within the Data Envelopment Analysis (DEA), while analysing the efficiency of public spending, actual expenditure is compared to minimal expense, which is enough to produce the same result (outcome). The method was developed by Debreu (1951) and Farrell (1957), later Färe et al. (1994), Seiford and Thrall (1990). DEA can be focused to inputs (1) or outputs (2). The first case (focus on inputs) examines how many inputs could be reduced without changing the output.

The second case (focus on outputs) examines how many outputs can be created without changing inputs. Both approaches examine the public sector efficiency and only slightly differ in results (Coelli et al., 2005).

#### ***Measuring public sector performance and efficiency***

The approach taken by A. Afonso, L. Schuknecht, and V. Tanzi (2003) can be considered very inspiring. In order to contribute to expressing and measuring of public sector performance and efficiency, they have suggested, first, the *public sector performance indicator* and, second, *public sector efficiency indicator*. As regards the expression and measurement of public sector performance, the authors base it on the assumption that the performance depends on the values of certain economic and social indicators ( $I$ ). Let us assume that there are  $i$  number of states and  $j$  number of territories where the government

operates, which together determine the overall public sector performance in the country  $i$  -  $PSP_i$  (from the English term Public Sector Performance). We can, thus, write that:

$$PSP_i = \sum_{j=1}^n PSP_{ij} \text{ where} \quad (1)$$

$$PSP_{ij} = f(I_k)$$

It can be assumed that the growth of public sector performance depends on improving of the values of the selected socio-economic indicators:

$$\Delta PSP_{ij} = \sum_{k=1}^n \frac{\partial f}{\partial I_k} \Delta I_k \quad (2)$$

Seven socioeconomic indicators have been chosen as sub-indicators of an aggregate indicator of public sector performance, three of which relate to the government basic fiscal functions, four are related to public administration, education, healthcare, and public transport infrastructure. Other factors and variables (see diagram) have been selected to express these indicators.

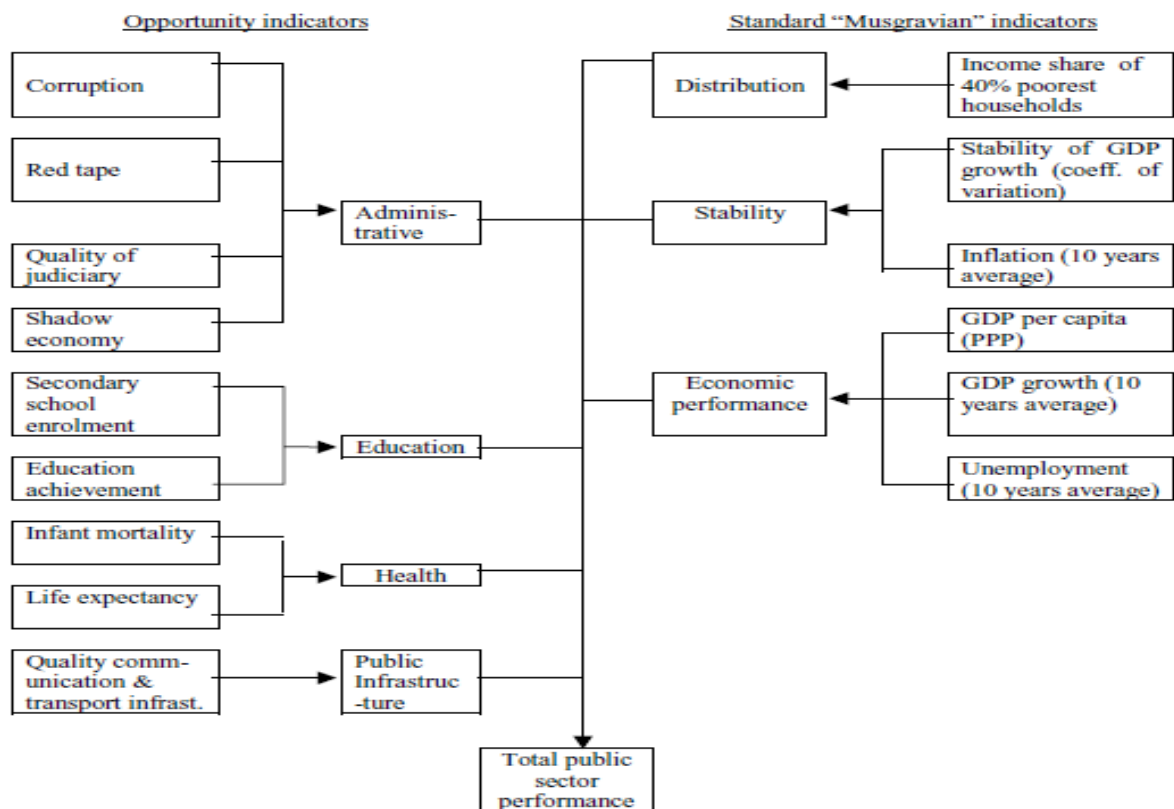

Fig. 1 - Total public sector performance (PSP) indicator. Source: Afonso, A., Schuknecht, L., Tanzi, V. (2003).

With regard to the efficiency of public spending, the authors have attempted to define an indicator of the overall public sector efficiency. This indicator of the overall efficiency is for a country,  $i$ , as follows:

$$PSE_i = \frac{PSP_i}{PEX_i}, \text{ where} \quad (3)$$

$$\frac{PSP_i}{PEX_i} = \sum_{j=1}^n \frac{PSP_{ij}}{PEX_{ij}} \quad (4)$$

An indicator measures the public sector performance (PSP) with expenditures to achieve it (PEX - Public Expenditure).

Expenditures for assets and services, transfers, purposeful expenditures for education and healthcare, and public investment have been included in the aggregate public expenditure.

The analysis of the efficiency of public spending has been carried out using the FDH method. FDH is a non-parametric method suggested by Deprins, Simar, and Tulkens (1984). Through this method, manufacturers can be sorted according to manufacturer's efficiency by comparing each individual performance with the so-called production possibility frontier, which ensures the highest possible output for a given level of inputs and vice versa – it is possible to determine the lowest level of input required to achieve a given level of output. Public expenditures, as a percentage of GDP, measure inputs and outputs, which are already expressed by a comprehensive indicator of the public sector performance.

Fig. 2- Production possibility frontier, 23 OECD countries, 2000. Afonso, A., Schuknecht, L., Tanzi, V. (2003).

The figure shows that the most efficient countries are Japan, USA, and Luxembourg, while EU countries are inside the production possibility frontier. The average input efficiency for 15 EU member countries is 0.73; this means that they should be able to achieve the same output with 73% of commonly used inputs; an average score of non-EU countries in the OECD is 0.89 inputs.

The study of A. Afonso, L. Schuknecht, and V. Tanzi (2006) on the public sector efficiency in the new EU Member States and emerging markets has been another that significantly contributed to the field. In this study, the authors extend the discussion regarding the expression and measurement of effectiveness, analyse Public Sector Performance (PSP) and efficiency (PSE), and apply DEA analysis. Unlike in the previous study, the authors have slightly changed some indicators within the PSP.

The DEA method has been applied by Afonso et al. (2005) to estimate the efficiency of some public sector areas (between 1980 and 1990), and Afonso, Aubyn (2005) to analyse the efficiency of education and health. This method has been applied by Gupta et al. (2001), Sijpe

Rayp (2007), and Afonso et al. (2006) to analyse the situation in the public sector in developing countries. Balaguer-Coll et al. (2007) applied DEA to analyse the efficiency of local authorities in Spain.

While Afonso et al. (2005) examined PSE in seven public sector segments, Angelopoulos, Philippopoulos, and Tsionas (2008) focused on four segments, namely: education, administration, infrastructure, and stabilization. Based on data from 52 countries (for the period between 1995 and 2000), the authors have attempted to calculate the so-called technical efficiency (TE) of public expenditures, using the so-called Stochastic Frontier Analysis. Subsequently, using the PSE and TE within econometric models, they have examined the relationship between the public sector size (extent) and economic growth. In their opinion, this relationship is affected by the so-called size-efficiency mix.

In terms of shift in public sector efficiency research, this approach constitutes a further step to achieve greater reliability of economical and analytical instrumentation and, at the same time, confirms that the efficiency can be measured despite great difficulties with the selection of appropriate indicators. This is supported by further research.

As emphasized by Hauner and Kyobo (2008), it is logical that current literature examines the factors influencing differences in efficiency between countries in different public sector areas. Hauner and Kyobo (2008) examine the factors of public expenditures efficiency in Russia and comes to the conclusion that a higher efficiency is associated with higher income per capita, smaller proportion of federal subsidies in incomes of lower segments of administration, better governance, stricter democratic control, and lower government spending.

Hauner and Kyobo (2008) completed the first large panel for the field of education and health based on data from 114 countries of different income levels for the period between 1980 and 2006 with approximately 1800 annual observations in individual countries in order to analyse the factors influencing the efficiency of public spending in these areas. The authors calculated the three types of indicators for each country:

- Indicators of Public Sector Performance - PSP, measuring only the results (outcomes);
- Indicators of Public Sector Efficiency - PSE, measuring the results (outcomes) and expenditures;
- Data Envelopment Analysis - DEA, measuring efficiency in relation to the production possibility frontier.

In the second part of research, these authors tied the obtained results to a set of factors from the economic, demographic, and institutional field and by means of regression analysis examined their effect on the efficiency. The most important conclusions were the following:

- Higher volume of expenditure in relation to GDP leads to lower efficiency,
- Within the efficiency of expenditures for education and health, other factors play its role (e.g., that the corruption worsens the efficiency, that the relatively younger population decreases the performance and efficiency in education, while a higher population density increases performance, etc.).

For their analysis, the authors applied public sector indicators (PSP) and public sector efficiency (PSE) indicators proposed by Alonso et al. (2005) and the Data Envelopment Analysis (DEA) method. In all three cases, the results (outcomes) are the baseline indicators for the analysis.

Authors Donath and Maurius (2008) emphasize the importance of data based on COFOG (Classification of the Functions of Government) classification of public expenditure for a

deeper analysis of public sector efficiency. With regard to the difficulties of comparing the results of the activities of different public sectors, the authors focus their attention only on education and health. Given the progress made in these two areas, in terms of indicators and their international monitoring, it is completely understandable.

A. Afonso, A. Romero, and E. Monsalve (2013) have followed up on previous research made by A. Afonso, L. Schuknecht, and V. Tanzi (2005 and 2010) in the analysis of public sector efficiency in twenty countries of South America and three in Caribbean countries. The results of this analysis fully corresponded with the conclusions of the previous two studies.

The research focused on the public sector efficiency, taking into account the effect of other factors, such as fiscal decentralization, competition between jurisdictions, political and budgetary institutions, fiscal capacity, democratic participation, etc., is also very inspiring. The analysis of these factors is a focal point of research conducted by D. Becker (2008), A. Antonis, D. Manthos and K. Pantelis (2008), T. Curristine, Z. Lonti, and I. Joumard (2007), L. Borge et al. (2007), and others. Similar processes can be considered beneficial because they enable to fill in more white space of the compiled mosaic about the image of public sector efficiency.

Becker (2008) analyses the public sector efficiency in 74 countries around the world (in 1985, 1990, 1995 and 2000) using the methodology of Afonso et al. (2005). Based on the application of non-parametric FDH and DEA methods to assess the public sector efficiency, the author reaches conclusions, which he subsequently confronts with the intensity of the so-called inter-jurisdiction competition. Becker made the following conclusions:

- The level of public sector efficiency can be partly explained by the so-called continental factors based, for example, on a shared history and culture;
- Smaller governments are more public sector effective, even though it can not be argued that they are closer to the efficiency frontier; countries that were able to achieve that have a medium-sized public sector compared to other analysed countries;
- Globalized countries tend to be more efficient (although this effect is not so strong);
- Competition between jurisdictions plays a key role in the public sector efficiency;
- More centralized countries in the sample were more effective, although even this result was not significant.

However, the author emphasizes that the results of his study do not necessarily confirm the view that a higher degree of competition between jurisdictions (between countries or local authorities within these countries) automatically means higher public sector efficiency.

Antonis, A., Manthos D. and Pantelis K. (2008) analyse the impact of decentralization on the Public Sector Efficiency - PSE in 21 OECD countries between 1997 and 2000 using DEA. The effort is to propose two alternative PSE indicators reflecting the government's objectives in the area of economic development and stability. On the basis of the methodological knowledge of Simar and Wilson (2007) and Khan and Lewbel (2007), the authors attempt to confront the results of the PSE analysis with a group of indicators of fiscal decentralization. These authors characterized the degree of fiscal decentralization in two ways [according to GSF and according to Stegarescu's proposal (2005b)]. The conclusions of this experiment to study the effect of fiscal decentralization on the public sector efficiency are clear: the growth of fiscal decentralization promotes the growth of efficiency.

Is the efficiency of public sector services influenced by political and budgetary institutions, fiscal capacity, and democratic participation? This question was posed by Borge et al. (2007) in their research based on the so-called new global level of efficiency for local government in

Norway. The authors believe that the increased public sector efficiency means an increase in the volume of its services without increasing costs. It is considered an important factor for increasing the governments' economic performance. Factors conditioning the so-called global efficiency were previously analysed, for example, by De Borger et al. (1994), De Borger and Kerstens (1996), Ashworth et al. (2006) using data for Belgium, or Hayes and Chang (1990) and Hayes et al. (1998), using data for the USA, or Balaguer-Coll et al. (2007), using data for Spain. Studies that have been compiled in Norway focus rather on measuring the efficiency of individual public services in healthcare or education.

Since 2001, Norway has published data from the so-called aggregate output of six kinds of public sector services (care for the elderly, primary and secondary education, day care, social benefits, custodial care and basic healthcare). The Norwegian Advisory Commission on Local Government Finances has developed levels of the so-called aggregate output. This level of aggregate output consists of 17 indicators of production in all six kinds of public services. Each of these defined indicators is assigned weight according to the share of public expenditure in total expenditure of any particular public sector services (in terms of sub-indicators) or across the public sector (in the case of all six types of public services). On this basis, the authors analyse the links between the public sector efficiency, on the one hand, and political and budgetary institutions (1), fiscal capacity (2), and democratic participation (3), on the other.

To indicate the influence of political power, the authors apply the so-called Herfindahl index that enables one to measure this power through the fragmentation of political parties. The classification of political regimes and their division into four types was another indicator of political power. In this case, the authors used the approach of Kalseth and Rattsø (1998). Their conclusions about the influence of political power as measured by means of this classification, however, are ambiguous and differ from those of other similar studies (Borge, Falch, & Tovmo, 2007). T. Curristine, Z. Lonti, and I. Joumard (2007) define efficiency as costs per unit of output. Measuring efficiency requires quantitative information about costs (or inputs in tangible terms). An accrual accounting system, which covers costs, can be considered better for this purpose than the system of cash flows. While measuring efficiency, it would be ideal if we could cover not only quantitative, but also qualitative aspects of public services, which still, however, causes difficulties.

#### **4 CONCLUSION**

Little attention has so far been paid to the public sector efficiency research in the Czech Republic, especially methods of its analysis. F. Ochrana has been for long dealing with this issue. He mainly focuses on the theoretical aspects of the cost-benefit analysis and the issue of using the selected methods (CMA, CBA, CEA, CUA, etc.). F. Ochrana (2007) also proposes steps to apply selected methods of evaluating the efficiency of institutions in the public sector based on situational analysis in the Czech Republic.

Regarding the application of the DEA method in the public sector in our country, the list of surveys and studies is even more limited. We can mention, for example, the outputs of GA CR project: Models and methods of evaluating the efficiency of public and private sectors ("Modely a metody hodnocení efektivnosti ve veřejném a soukromém sektoru"). This project No. GA 402//01/0133, person responsible: J. Jablonský, University of Economics, Prague 2001-2003. M. Dlouhý, V. Pánková (2003) and M. Dlouhý, J. Jablonský and I. Novosadová (2007) applied the DEA method in evaluating the efficiency of healthcare.

It can be concluded that the application of selected methods of public sector efficiency analysis, its segments, and institutions have a great perspective in the Czech Republic.

Research focus on various aspects of this efficiency can be beneficial not only for the development of the theory, but also for economic policy and practice.

## **MULTI-CRITERIA ANALYSIS FOR THE MOST EFFICIENT SELECTION OF BANK ACCOUNT FOR YOUNG PEOPLE**

*Martina Hedvicakova, Alena Pozdilkova*

### **Abstract**

Due to the growing competition in the banking market, banks try to attract potential clients as soon as possible and target their offers at students of secondary schools and universities and young people up to 30 years. They offer free accounts and attract young people to the various benefits. The aim of the paper is to compare all the options available on the market (student accounts, accounts for the young and standard accounts). Using multi-criteria analysis the best accounts will be chosen based on selected criteria for two defined profiles - Active and Inactive clients. The overall results of each type of bank account will be compared with each other and the most advantageous account for young people will be selected.

*Key words: bank, account, multi-criteria analysis, costs, client.*

JEL Classification: G21, C58, C610

## **1 INTRODUCTION**

In the Czech Republic there are currently 44 banks and branches of foreign banks (Czech national bank, 2015). The number of banks is much higher than for example in Slovakia, where the market is smaller. This situation leads to high competition in the market and constantly finding new offers, packages and marketing campaigns. One of the target groups are young people under thirty years of age. This group can choose from different types of bank accounts. If they are still students, they are targeted by student accounts. When they meet the age requirement, e.g. they are up to thirty years, they can choose from accounts offered for young people (e.g. Komerční banka offers the G2.2 Account (26-30 years), UniCredit Bank offers a U Account for young people etc.). This offer is smaller than that of the student accounts. Last but not least, they can choose any standard bank account, preferably from a "low-cost" bank such as mBank or FIO, which have no account maintenance retail fees. It always depends on the specific requirements on the bank account or the benefits that banks provide, or the availability of ATMs, level of online banking or smartbanking. The aim of this paper is using multi-criteria analysis to select the most appropriate account for two client groups: active and inactive.

## **2 THEORETICAL BASES**

From a functional point of view, the bank described as a financial intermediary, whose main activity is the acceptance of deposits, provides loans and execution of payments. (Revenda, 2011; Polouček, 2009)

The perception that banks are exploiting customers through their fee-charging practices in a bid to maximize profits, has fuelled widespread public interest in identifying the banks that profit most heavily from fees. (Tennant, 2014)

European Union Directorate-General for Health and Consumers Protection focuses on tariff transparency, client mobility and easier product comparison improvement. In accordance with these efforts in 2010 in the Czech Republic there was launched an independent retail core

banking services calculator project (hereinafter as Calculator). Its purpose is to compare bank fees of different accounts based on demanded services and price. Each customer inputs his or hers usage pattern and the RCBS Calculator suggests the cheapest alternative on the market in the Czech Republic. (Hedvicakova, Soukal, 2012).

A young person up to thirty years of age can choose from the following three types of bank accounts:

#### **a) Student accounts**

Student accounts are restricted by the condition of study at secondary school or university and by age - usually 15 to 26 years. These accounts are promoted by banks as the best for young people. Account management is free, but it is often subject to conditions such as a minimum number of ATM withdrawals per month or a minimum monthly turnover on the account etc. These conditions are often unwieldy for students and this leads to an increase in costs for the management of student accounts. Banks also try to lure students to various benefits such as free backpacks, flash drives when opening an account, ISIC card for free, discounts in shops etc. Banks are based on the assumption that the Czech client is conservative and does not often change their bank. They hope that after their graduation, students will remain at the same bank, and the bank immediately convert the student account to a standard account which is already charged.

#### **b) Accounts for young people**

Accounts for young follow a student account, as it is in the case of Komerční banka and its G2.2 Account. It is designed for people from 26 to 30 years of age. If young people want a free account, this account is also debited with conditions and it is necessary to meet at least one of them: a regular income; loan, credit or mortgage from KB; savings deposited in KB or to be saving or investing at KB. (Komerční banka, 2014)

#### **c) Standard bank accounts**

As mentioned above, in the Czech Republic there are currently 44 banks, 6 of which do not provide a full range of banking services, but focus on one or a few types of banking products, e.g. Hypoteční banka, Česká exportní banka and others.

Other banks provide different accounts for different groups of customers with similar requirements. Today, there are very modern products and services packages that are free or for a fee known in advance. In most cases, the client pays more than the bank declares with the package, because they exceed the pre-determined number of operations.

In the last five years the so-called "low-cost" banks began to appear. These are banks, where account management is free, but they do not provide all the products or services such as payment orders abroad, they do not have a physical location or ATMs, etc.

The first low-cost banks in our country include mBank, FIO, Equa bank, Air bank, ZUNO.

### **3 OBJECTIVE AND METHODOLOGY**

The aim of this paper is to confirm the scientific issues:

- A) Are student accounts for young people more advantageous than basic accounts from low-cost banks?
- B) How much extents do the offers made by the banks according to the monitored criteria?

This paper aims to select the best bank account of all kinds (student accounts, accounts for the

young, standard accounts) accounts offered on the Czech market. For selecting the most suitable bank account the multi-criteria analysis will be used.

For the analysis of basic accounts from low-cost banks will be used the following methodology.

To choose the best bank account with the lowest account management costs, data from the bank charges Calculator (hereinafter Calculator) will be used, which is available from: <http://www.bankovnipoplatky.com/kalkulator.html>. The aim of the Calculator is to compare the services and products of individual retail banks in the Czech Republic within the offer of basic banking services. The Calculator provides a calculation and comparison of individual banks based on individual demand of banking clients. According to the bank account statement, a client fills the questionnaire in seven steps and the results will outline the most appropriate accounts (in terms of cost). Due to maximum accuracy of the data, the form does not include questions regarding irregular activities - for example, one-off establishment of a service or change processes (change of address, PIN, standing order, etc.). (Bankovní poplatky, 2014)

The data are evaluated monthly and quarterly by Martina Hedvičáková (co-author of the paper) and Ivan Soukal. The bank charges Calculator has been used by 88,711 bank customers so far. In the first part of this paper will be used data for the fourth quarter 2014. In this quarter the Calculator's services used 1238 respondents.

In terms of marketing research, it includes the following data:

- **multi-dimensional** - 54 variables are monitored on the use of service, 2 system variables for each element in the set and 45 variables regarding pricing on individual accounts,
- **primary** – data was obtained directly from the users of banking services,
- **subjective** - data based on the client's judgment regarding their own use of banking services. (Bankovní poplatky, 2014)

Based on the data obtained from the Calculator, the Client and the Bank index are calculated.

Calculations and statistical analysis were performed using the statistical IBM PASW 18 software (formerly SPSS) and MS Excel 2013. Calculation is performed on a monthly and quarterly basis for the selection of the population obtained in the reference month or quarter. The calculation precedes verification-validation part to avoid skewing of results e.g. by the respondents who should not use the retail products (self-employed individuals, small businesses with the frequency of use of banking services, which in practice a client can never reach with a civil account), and the respondents who only clicked through the form without filling the key services. (Bankovní poplatky, 2014; Draessler et al, 2011)

#### **a) Client index**

The Calculator follows the behaviour of clients very closely and captures the use of retail banking services of respondents. The Calculator therefore reflects accurate costs that the clients actually pay to their banks. It is a precise monitoring of tariff headings: mainly the number of times the clients use the services and the amount they are charged. For this reason, if it is an active client then in an averagely expensive bank they will pay hundred crowns monthly. If someone hardly ever uses a bank, then even in an expensive bank they can get below 100 CZK per month.

The methodology for calculating the average cost per account is based on information regarding the bank as well as the particular account. The average costs of a particular account

are obtained by the arithmetic average of the clients computed by the Calculator, who have chosen the monitored account. This methodology is more accurate, but it requires a greater number of clients. The number of accounts with a lack of respondents for calculation is much higher. More information on the methodology of calculation: <http://www.bankovnipoplatky.com/klientsky-index---metodika-12507.html>. (Hedvicakova, Soukal, 2014)

### **b) Banking index**

An alternative view on fees is provided by Banking index, which analyses the best bank accounts for 4 main groups of clients (Active, Branch, Average internet, Passive internet).

The calculation methodology is available from <http://www.bankovnipoplatky.com/bankovni-index---metodika-12509.html>. (Soukal, Hedvicakova, 2014)

**c) For the analysis of accounts for young people** will be used the following methodology.

Multi-criteria decision-making and evaluation of alternatives will be used, where the criteria are as follows. (Huang, Keisler, Linkov, 2011) The first set of criteria will be fee criteria, which include fees for account management, fee for incoming and outgoing payments, fees for standing orders and fees from the merchant (including the number of payments and the total amount).

Another possible selection criterion could be fees for mobile and internet banking, which is especially very often used by young people, but nowadays the bank offers are comparable and almost all institutions offer these services for free. Therefore, it is unnecessary to include them in the ranking. (Ekel, Martini, Palhares, 2008)

Plus as other criteria for selecting the most suitable account, we will consider the benefits offered and the availability of ATMs, which will now be described in detail. (Jablonsky, 2007)

One of the most important criteria when choosing an account is also the availability of ATMs, because the service is extensively used especially by young people and can influence the selection of their future bank and account in both ways positively as well as negatively (if the ATM's network of the selected institution is inadequate in the location). The top coverage of ATM's network belongs to Komerční banka and ČSOB, which offer more than 700 ATMs across the Czech Republic (plus it is also necessary to consider ERA Poštovní spořitelna, which has ATMs shared with ČSOB).

The above criteria will be used in multi-criteria decision-making and evaluation of the alternatives. Firstly, it will be necessary to determine the importance that will portray the significance of each criterion. (Dostal, 2008), (Mikulecky, Lenharcik, Hynek, 2002)

The importance of each individual criterion will be used in a standardized form:

$$v_j \geq 0, j = 1, \dots, m, \sum_{j=1}^m v_j = 1 \quad (1)$$

The overall evaluation of variants is determined by using utility function as follows:

$$u(x) = \sum_{j=1}^m v_j u_j(x) \quad (2)$$

in which  $v_j$  represents standardised importance of individual criteria and  $u_j(x)$  represents the evaluation of each variant. (Talasova, 2003)

Importance for individual criteria and all results will be shown in a separate chapter.

#### 4 SELECTING THE BEST BANK ACCOUNT ACCORDING TO AVERAGE MONTHLY COSTS

If young people choose an account according to the lowest average monthly costs, then in the last quarter of 2014 the following accounts turned out to be the best, i.e. up to 60 CZK:

Tab. 1 - Accounts and average costs in CZK, Source: (Soukal, I., Hedvicakova, M., 2015)

ACCOUNT	The average costs in CZK
Equa bank Běžný (active client)	12
AirBank Malý tarif	24
Fio Běžný	32
mBank mKONTO	57

Fig. 1 - Average costs for individual accounts. Source: own

Table 1 is missing Raiffeisenbank bank with eKonto Smart and UniCredit Bank with U Account, GE Money Bank with Genius Free & Flexi with which the clients should fit within the 60 CZK boundary, but there were either an insufficient number clients (as in Raiffeisenbank bank and UniCredit bank) or according to the Client index for fourth quarter of 2014 they did not fit into the boundary.

The following four banks Equa bank with Current account, Air Bank with Small tariff, Fio with Current account and mBank with mKonto will be further calculated for the Active and Passive client according to the multi-criteria analysis.

The Client index (table 1) order is determined solely on the basis of the average monthly costs. This analysis does not take other aspects into account that may be important for the client, such as the availability of ATMs, benefits offered, physical location of a bank branch, the level of smartbanking etc. These criteria will be used in multi-criteria analysis in the next section.

## 5 THE SELECTION OF CRITERIA FOR MULTI-CRITERIA DECISION-MAKING

For the comparison of individual accounts, we will use multi-criteria decision-making and evaluation of alternatives defined in methodology section.

For the above defined criteria we define the importance as follows:

Tab. 2 – Standardised importance of individual variants. Source: own.

CRITERION	Standardised importance
Management account fees	0.10
Fees for incoming payments	0.05
Fees for outgoing payments	0.15
Fees for standing orders	0.05
Fees from a merchant	0.20
Benefits	0.20
Availability of ATMs	0.25

Fig. 2 – Standardised importance of individual variants. Source: own

## 6 CLIENT PROFILES

Now let's have a look at two typical profiles of young people due to the use of banking services, which we will continue to call active and inactive profile.

An inactive profile will represent a young client who uses their account relatively little. They have a monthly average of 2 ATM withdrawals, 2 outgoing payments (such as food and one order from the internet) and 2 incoming payments (they receive pocket money from parents and an income from a part-time job). They use one standing order for regular payment for accommodation. Payments at a merchant are very often used especially by young people (very few young people pay by cash); this model profile has 5 payments at a merchant per month totalling 1,000 CZK.

In contrast, the active profile will represent a young person who frequently use their account and tries to use the benefits of this account. They have a total of 5 ATM withdrawals per month, 4 outgoing payments (orders from the Internet are paid via the account, not by COD) and 2 incoming payments (due to their age they have income only from their parents and from a part-time job). They also have only one standing order same as the previous type, which is used for the payment of accommodation. Payments at a merchant, however, are used on a regular basis, they have 15 of them per month totalling 2,500 CZK.

Internet and mobile banking is used by both defined profiles, but since it is now a standard matter, we will not consider it in the further comparison.

## **7 THE RESULTS OF THE MULTI-CRITERIA ANALYSIS FOR THE 4 SELECTED CURRENT ACCOUNTS**

Four similar accounts were chosen for the multi-criteria analysis for which the cost calculation was carried out using client index, i.e. Equa bank Běžný (active client), Air Bank Malý tarif, Fio Běžný účet and mBank mKONTO (Equa bank, 2014; Air bank, 2014; FIO, 2014; mBank, 2014). The multi-criteria decision-making was performed for these accounts for the two defined above client profiles in accordance with these 7 criteria.

The following table 3 describes the overall value of the totality of fee criteria at selected banks for the inactive profile

Tab. 3 – Overall value of the totality of fee criteria at selected banks for the inactive profile.  
Source: custom processing from pricelist of the banks

<b>ACCOUNT</b>	<b>Total monthly charges in CZK</b>
Equa bank Běžný (active client )	0
Air Bank Malý tarif	-4
Fio Běžný účet	0
mBank mKONTO	18

The following table 4 describes the overall value of the totality of fee criteria at selected banks for the active profile:

Tab. 4 – Overall value of the totality of fee criteria at selected banks for the active profile.  
Source: custom processing from pricelist of the banks

<b>ACCOUNT</b>	<b>Total monthly charges in CZK</b>
Equa bank Běžný (active client )	0
Air Bank Malý tarif	21
Fio Běžný účet	30
mBank mKONTO	88

Another important criterion is the benefits offered, which in the four selected banks are as follows:

Air bank offers advantageous interest (as the only one from the offered accounts) and also the possibility of withdrawals from the terminals of Sazka. Equa bank offers free withdrawals from all ATMs in the Czech Republic as well as online payments without charges. Fio banka, same as mBank offers free incoming and outgoing payments, standing orders, withdrawals at a physical branch and a certain number of withdrawals from ATMs of another as well as their own banks.

The following table 5 evaluates the overall level of benefits of the individual accounts (linguistically defined variable) including the assigned standardised evaluation:

Tab. 5 - Overall level of benefits of the individual accounts. Source: own

<b>ACCOUNT</b>	<b>Level of benefits</b>	<b>Evaluation</b>
Equa bank Běžný (active client )	Average	0.5
Air Bank Malý tarif	Very good	0.7
Fio Běžný účet	Excellent	1
mBank mKONTO	Excellent	1

Availability of ATMs is compared in the following table 6, which reflects the degree of availability while using the linguistically defined variables, expressing the availability degree of ATMs of a given bank. It is divided into the range of high availability, average availability, low availability. The value of withdrawals anywhere is superior to these values. The table also includes a standardised evaluation of linguistically defined variables.

Tab. 6 - Comparison of the accounts according to the availability of ATMs. Source: own

<b>Bank</b>	<b>The total number of ATMs</b>	<b>Availability ATMs</b>	<b>Evaluation</b>
Equa bank	-	Withdrawals anywhere	1
Air bank	52 + terminals of Sazka	Average availability	0.5
Fio bank	153	Average availability	0,5
mBank	-	Withdrawals anywhere	1

The results for individual banks are clearly expressed in the following table 7.

Tab. 7 - Results for individual banks. Source: own

Bank	The evaluation for an inactive client	The evaluation for an active client
Equa bank	0.79	0.9
Air bank	0.815	0.705
Fio bank	0.765	0.71
mBank	0.725	0,67

Fig. 3 - Results for individual banks. Source: custom processing

The multi-criteria analysis for the profile of an inactive client evaluated the AirBank account as the best, because it had the best values of fee criteria and relatively advantageous benefits. Conversely, for an active client the Equa bank account was evaluated as the best, which also had the best values of fee criteria and withdrawals from any ATM free of charge.

## 8 THE RESULTS OF THE MULTI-CRITERIA ANALYSIS FOR THE SELECTED STUDENT ACCOUNTS

Apart from low-cost current accounts, student accounts are a highly beneficial product for young people. Six accounts were selected for the multi-criteria analysis, which are the best in terms of fee, i.e. ČSOB Student account, The U account for young people from UniCredit Bank, FRESH account from Česká spořitelna, Era personal account for young people from Poštovní spořitelna, G2.2 Account from Komerční banka and Genius Student account from GE Money Bank (Komerční banka, 2014; ČSOB, 2014; UniCredit Bank, 2014; Česká spořitelna, 2014; ERA, 2014; GE Money Bank, 2014). Multi-criteria decision-making was carried out in accordance with these 7 criteria for these accounts for the two client profiles defined above.

The following table 8 describes the overall value of the totality of fee criteria at selected banks for the inactive profile:

Tab. 8 – Overall value of the totality of fee criteria at selected banks for the inactive profile.  
Source: own

<b>ACCOUNT</b>	<b>Total monthly charges in CZK</b>
ČSOB Student account	0
UniCredit U account for young people	0
ČS FRESH account	16
Era personal account for young people	16
KB G2.2 Account	18
GE Genius Student	20

The following table 9 describes the overall value of the totality of fee criteria at selected banks for the active profile:

Tab. 9 - Overall value of the totality of fee criteria at selected banks for the active profile.  
Source: own

<b>ACCOUNT</b>	<b>Total monthly charges in CZK</b>
ČSOB Student account	35
UniCredit U account for young people	0
ČS FRESH account	77
Era personal account for young people	60
KB G2.2 Account	58
GE Genius Student	72

Another important criterion are the benefits offered, which in the six selected banks are the following.

The ČSOB Student account offers free incoming and outgoing payments, ATM withdrawals from own bank, credit card with overdraft and smartbanking. The UniCredit U account for young people offers free incoming and outgoing payments, standing orders, withdrawals from ATMs of any bank and smartbanking. The ČS FRESH account provides free all incoming payments and 2 withdrawals from ATMs from own bank. The Era personal account for young people offers free incoming payments, 2 ATM withdrawals and overdraft free of charge. The KB G2.2 account offers annual bonuses and bonuses for payments at merchants in the form of withdrawals from ATMs free of charge. The GE Genius Student provides free incoming payments and standing orders, and all withdrawals free from ATMs of own bank.

The following table 10 evaluates the overall level of benefits of individual accounts (linguistically defined variable) including the assigned standardised evaluation to them.

Tab. 10 – Overall level of benefits of individual accounts. Source: own

<b>ACCOUNT</b>	<b>Level of benefits</b>	<b>Evaluation</b>
ČSOB Student account	Very good	0.9
UniCredit U account for young	Excellent	1
ČS FRESH account	Below average	0.4
Era personal account for young	Below average	0.4
KB G2.2 account	Below average	0.4
GE Genius Student	Average	0.6

The availability of ATMs is compared in the following table 11, which reflects the degree of availability while using the linguistically defined variables, expressing the availability degree of ATMs of a given bank. It is divided into the range of high availability, average availability, low availability. The value of withdrawals anywhere is superior to these values. The table 11 also includes a standardised evaluation of linguistically defined variables.

Tab. 11 – Availability of ATMs. Source: own

<b>ACCOUNT</b>	<b>The total number of ATMs</b>	<b>Availability of ATMs</b>	<b>Evaluation</b>
ČSOB Studentské konto	874	Very good	0.7
UniCredit U konto pro mladé	200	Withdrawals anywhere	1
ČS FRESH účet	1497	Excellent	0.9
Era osobní účet pro mladé	72+874 ČSOB	Very good	0.7
KB Konto G2.2	703	Very good	0.7
GE Genius Student	699	Very good	0.7

The results for individual banks are clearly expressed in the following table 12.

Tab. 12 – Results for individual banks. Source: own

<b>ACCOUNT</b>	<b>Evaluation for non-active profile</b>	<b>Evaluation for active profile</b>
ČSOB Studentské konto	0.905	0.795
UniCredit U konto pro mladé	1	1
ČS FRESH účet	0.69	0.58
Era osobní účet pro mladé	0.64	0.585
KB Konto G2.2	0.585	0.585
GE Genius Student	0.57	0.57

## **9 DISCUSSION FOR THE MULTI-CRITERIA ANALYSIS OF THE SELECTED STUDENT ACCOUNTS**

Is it more advantageous for a young person to choose a standard current account, which presents itself as low cost or use the targeted banks' offers for young people or directly for students? Accounts for young people also offer a range of benefits targeted at this group. Using multi-criteria analysis, 4 similar accounts were chosen for which the cost was calculated using the Client index, i.e. Equa bank Běžný, Air Bank Malý tarif, Fio Běžný and mBank mKONTO. According to the 7 criteria described above, multi-criteria decision-making was carried out for two profiles: active and inactive client. The best account for an inactive client seemed to be the Malý tarif from AirBank, which had the best values of fee criteria and relatively advantageous benefits. Conversely, for an active client the best account seemed to be Běžný from Equa bank, which also had the best values of fee criteria and withdrawals from any ATM free of charge.

If we compare the results of the multi-criteria analysis using low-cost accounts with student accounts, the best was the U account for young people, in terms of both bank charges as well as withdrawals from all ATMs free of charge, calculated for an active as well as inactive client.

This confirms the first scientific issue that student accounts are for young people more advantageous than basic accounts from low-cost banks.

The second scientific issue was demonstrated on two client profiles. Results are shown in tables in relevant section (see Tab. 10 and Tab. 11), where all criteria are described. Differences between banks are significant and depend on the preferences of individual users, two defined profiled show different results.

The offer of accounts for young people is very diverse in the market; it always depends on personal criteria and requirements for a bank account. Precise definition and choice of their evaluation is the basis for selecting the correct account.

## **10 CONCLUSION**

If a young person wants to choose the best account, they have several options. They can carefully examine all scales of individual banks or they can use online comparators freely

available on the web. Both of these options assume perfect knowledge of all monthly operations that the client will carry out. However, it does not take into account other criteria that may be important for clients, such as the availability of ATMs, physical location of bank branches, smartbanking level, etc. For this reason, the first part of the paper used data from the bank charges Calculator and ranking of the most beneficial standard current accounts up to 60 CZK per month was created regardless of other criteria.

In the next part of the paper, 2 profiles were set: Active and inactive client and according to seven criteria the best bank account was chosen for each profile. For simplicity, only 4 banks were analysed, which the Calculator evaluated as the cheapest and they fit into the 60 crowns border.

These banks are referred to as low-cost banks, but they do not provide such a wide range of products and services. Using multi-criteria analysis, the best for an Inactive client is the Malý tarif from AirBank, which is characterised by the best fee criteria and relatively favourable benefits. For an Active client the best seems to be Běžný účet from Equa bank, which also had the best values of fee criteria and withdrawals from any ATM free of charge. This assessment is consistent with the results from the bank charges Calculator.

Young people are targeted also with student accounts, which were analysed in the last section. Six student accounts were selected, which seem to be the best regarding fees according to the tariff terms of individual banks. According to same seven criteria used in the previous analyses, multi-criteria decision-making for the two client profiles was carried out. For both profiles: Active as well as Inactive, taking into account only the fee criteria, the most favourable is UniCredit bank with the U account for youngsters, which has free account management. An inactive client can also choose the ČSOB Student account, which is also free of charge. For an inactive client it does not matter if they select the standard bank account or a student account. In both types of bank accounts they can fit into the 20 CZK boundary. For an Active client, the average monthly cost for maintaining the account range from 0 to 88 CZK. Young people who decide to actively use a student account should choose a standard current accounts rather than the student ones. However, it depends only on the person, how well they know their monthly payment operations, what benefits and services they require from the bank. Only then are they able to effectively decide what account to choose.

## **REGULATORY CAPITAL REQUIREMENT UNDER BASEL, THE ABILITY TO PERFORM OF VIETNAMESE COMMERCIAL BANKS**

*Ho Thanh Tung*

### **Abstract**

This study aims to analyze whether Vietnamese commercial banks may feasibly apply the regulation of Basel in the next few years. The study examines 10 Vietnamese commercial banks, which have been selected by The State Bank of Vietnam (SBV) to apply Basel regulation, during the period from 2003 to 2013. By employing the multi – regression, permutation – test and Granger – causal, the results show that adjusted turnover of loans, expenditure for interest and leverage would have an impact on banks' capital structure. Additionally, if both turnover of loans and expenditure for interest could be controlled as the same level of 2010, Vietnamese commercial banks may achieve the benchmark of the Central Bank.

*Keywords: Bank regulation, capital regulation, Basel regulation, leverage.*

JEL Classification: G21, G28

## **1 INTRODUCTION**

In an effort to establish a roadmap for banks of Vietnam to be more integrated with the international financial environment, SBV has issued a number of regulatory requirements and regulations governing activities of commercial banks of Vietnam, including regulation on minimum own capital issued in 2006, circular number 13/2010/TT-NHNN on prudential ratios, capital ratio, risk weight assets (RWA), maximum ratio of lending loans released in 2010 (see link from reference N<sup>o</sup>.15). Recently, SBV has selected ten commercial banks as the pilot to apply Basel regulatory (SBV N<sup>o</sup>. 1601/2014, 2014). This trial will begin in early 2015 and subsequently, all commercial banks in Vietnam are required to apply Basel regulatory in 2018.

Based on the analysis of data which was collected from annual report of Vietnamese commercial banks, in this writing, I will discuss about the possibility of implementation this in terms of (just about the) improvement the capital regulation, and focus on three following objective points. Firstly, I consider whether the changing trends of banks' capital in recent years have showed the readiness of banks for the standards applying. Secondly, I am going to find out whether there is a relationship among the changes in the inherent index performance indicators of the banks and which variable is the most important factor that banks should focus on for capital regulation. And lastly, I will find whether the trend directions are observed from business, the Vietnamese commercial banks may meet the regulatory requirements by the central banks or not.

Follow these points, section 2 of this writing is a short review from some studies that related to my research. In section 3, I will describe how data was collected and testing methods were used. Section 4 is the discussion about some main indicators and capital structure during 2003 – 2013. Section 5 is offered some conclusions.

## **2 THEORETICAL BACKGROUND**

### **2.1 Capital requirements, capital ratio and leverage**

Aggarwal & Jacques (1997) found the impact of The Federal Deposit Insurance Corporation Improvement Act (FDICIA) regulation on banks' long-term targets for the Tier 1 ratio and Michael & Perraudin (1998) study of UK bank data actually exceeds that convergence of the Tier 1 ratios to its long-run average is quicker. Actually, banks were more constrained by their leverage ratios than by the Basel-Accord Tier 1 and Tier 2 ratios. These studies may explain that when ratios based on narrow-equity measures, almost banks had chosen to raise its Tier 2 capital with Tier 1 adjusting subsequently. So, when analyzing on the data of Canadian banks from 1955 to 2009 Bordeleau, et al. (2009) argued that banks should have to have a constraint of leverage, and suggested that a leverage ceiling would be a useful tool to complement risk-weighted measures and mitigate procyclical tendencies in the financial system. More reinforced for capital structure studies, Ephraim Clark, et al (2014) showed that higher level of return on assets and/or a higher investment coefficient increase systemic volatility at all intervention banks. Given that, banks can increase their return on assets and their assets base by reducing their capital requirements; this evidences that a system of highly leveraged banks (high investment coefficients and high return on assets) is more volatile (less stable) and less sensitive to regulatory intervention than a system with higher capital requirements.

Study of Ruthenberg and Landskroner (2008) about loan pricing under Basel 2 suggested two approaches for capital requirements. These are internal and standardized. The reason of this suggestion was to adjust loan to the requirement of capital of Basel 2. Then Cipovová and Belás (2012) study risk approach under Basel 3, found advanced methods for credit risk measurement are more flexible on class change of corporate exposures in portfolio. Internal rating is the most used method in the Czech Republic, which worked out a much lower capital adequacy than The Standardized approach without assigned external rating. That means banks are trying to get profit from loans and avoiding to increase the capital for the risk weigh. Addition for loan pricing under Basel 2 & 3, Allen, et al (2012) had proved the reduction in cost of equity almost entirely offset the increase in funding that come from the shift from relatively low cost debt to relative high cost equity. So, the new requirements of capital will increase cost of funding a corporate loan portfolio to addition capital requirements but constraint on institutions with substantial exposure (low risk weighted assets), bank will reject to hold traded securities or mortgage lending.

### **2.2 Capital requirements and adjusting balance sheet**

Distinguin, et al. (2013) review some studies found that capital buffer and business cycle have positive two-way relationship. Negative co-movement with the cycle, capital buffer decrease during upturns or the contrary. The relationship of capital and liquidity is negative for small banks considering both liquidity creation measures. Authors employing the VAR model as formula. And with two definitions, these are Tier 1&2 capital to risk weighted assets (T12\_RWA) and Tier 1 capital to risk weighted assets (T1\_RWA). The result showed that indicators are replaced by one year lagged value. Running separate regression for US and EU banks with the variable environment, the results show that banks do not strengthen their regulatory capital when they face illiquidity issues. But as a new vision in research about Basel, in Cathcart et al (2014) study from data 1990Q1- 1992Q2 and 2007Q3 – 2009Q2 of US banks, quarterly growth rates for several asset categories on variables which regulators might be considered as financial indicators. These indicators of financial include Tier 1 ratios, total capital, total capital to risk-weighted asset ratios, leverage ratios, loans and mortgage

assets. Cathcart et al suggested that the ratio in risk weight capital should be flexible for the selection of capital target of bank.

### **3 METHODOLOGIES AND DATA**

I am using the panel data from annual report of all Vietnamese commercial banks in 2003 to 2013 for my analysis.

Firstly, I show the charts of some main financial indicators of 10 selected banks. The figures and charts are outline about capital facts of the ten Vietnamese banks, which have been chosen for the regulations applied.

Second, base on data and analysis of the first step, I choose a regression model fixed with data by employing Bayesian Model Average (BMA) method. This method will consult which model is the best model by pointing out which is the most explained the variation of the dependent variable. Then, from independent variables of model, I value the most important variable by using Lindermann – Merenda – Gold (LMG) method for test with Granger-Causation.

The Granger-Causation test of one dependent variable and one most independent variable is to focus on the most important indicator so banks should pay more attention to this indicator for a better result to improve capital regulation.

#### **3.1 Data**

The data used is panel data, which was collected from the annual reports of 40 banks of Vietnam from 2003 to 2013. In this period, some small banks had four year or less than four year of operation were removed from data. The data is disproportionate data, so when processing with R statistics language, a filter for missing data was used for a smooth result.

Data of 10 selected banks was taken from data of all banks above. Then from this data, I took total assets of 10 selected banks, which accounted for 50.2% of total assets of all Vietnamese banks as shown in *Fig.1*.

Fig. 1 – Tier 1 size of 10 banks to all Vietnamese commercial banks (Figures for Fig.1 are Total of these indicates, take data from data of all commercial banking industry of Vietnamese. Calculated by author. \*R statistics language.)

Ten figures representative indicators of capital and operation of bank were calculated at mean from data of the 10 selected banks, as summarized in Tab.1

Tab.1 – Indicates coded and Charts

Indicator	Code	Calculating	Shown on
Tier1 of banks	Tier1		Fig.2
Tier2 of banks	Tier2		Fig.3
Total assets of banks	TA	<i>Total Unweight Assets</i>	Fig.4
Own capital of banks to unweight total assets	OCA_UWA	$\frac{Tier1 + Tier2}{TotalUnweightAssets}$	Fig.5
Leverage	Leverage	$\frac{TotalLiability}{Tier1}$	Fig.6
Loans to customer of banks	LC		Fig.7
Deposit of customers in banks	DC		Fig.8
Expenditure for interest of banks	IEX		Fig.9
Return on equity of banks	ROE		Fig.10
Revenue from loans' interest of banks (only for description)	RI*		Fig.11

And all computing in many progresses, I used sources from panel data of 10 banks. From this group, I calculated the mean of some main indicators shown on the charts and transformed panel data as time series data for the Granger – Causation test.

### 3.2 Methodologies

- *Models and variable*

**First**, I employ the permutation test to test all 9 indicators to distinguish the variation value from two separated groups. This test is named "permutation test" (or randomization test, re – randomization test, exact test). This test method has an advantage that it tests for both parameters and non-parameters in compare between two groups. The result of this testing may give us a more consolidated explanation the trend from graphics. Those groups are control group and variation group and I can assign randomly for our two groups. In our case, I test to find out changing of banks from 2007 to 2013 has been more regulations or not.

Null hypothesis: the two groups have identical probability distribution, meaning the changing before and after 2008 is same. If p-value is close to zero, the changed significantly in period 2008 to 2013 is significant in compare with the changed of 2003 to 2007 period. Alternative hypothesis: the change is not significant between these periods. I expect that  $H_0$  won't be rejected as a good signal about the changing last time.

During the period from 1999 to 2005, capital ratio adequacy (CAR) had been mentioned by SBV, which indicated criterions about minimum of CAR for Vietnamese commercial banks. But until April 2006, The Central Bank issued the regulation to force commercial banks to enforce the regulations. So, data from 2003 to 2007 were grouped in two groups, one is from 2003 to 2007, the non-strictly compliant period about capital requirement and the second is from 2008 to 2013 strictly compliant period of capital regulatory.

**Second**, from representative indicated, I am going to choose the variable for our regression model. I take consultancy how many independent variables be in the best model by BMA method. This method proposes 4 models for selection.

Although *model 3* have all the variables but BMA method argue that application is based on BIC (Bayesian Information Criterion) index of this model is too small to be suitable (see Hoeting 1995). Therefore, I take *model 1* which have maximum BIC for explanation the variations of three main indications. They have been more affect to OCA\_UWA (Own capital on un-risk weight assets).

*Model 1* has three independent variables. These are IEX, LC and Leverage. Its form is:

$$Y_{it} = \beta_0 + \beta_1 X_{1it} + \beta_2 X_{2it} + \beta_3 X_{3it} + u_{it}$$

In my study, this model can be writing:

$$\text{OCA\_UWA}_{it} = \beta_0 + \beta_1 \text{IEX}_{it} + \beta_2 \text{LC}_{it} + \beta_3 \text{Leverage}_{it} + u_{it} \quad (1)$$

Where  $i(1,10)$  and  $t(1,11)$  are number of banks and the year in period, IEX is expenditure of banks for interest, LC is Loans from banks to customers.

Assumptions: Ten banks are same. IEX, LC, Leverage have normal distribution,  $u_{it} \sim N(0, \delta^2)$ .

The regression result of (1) by pooling data is shown on Tab.4

Result from Tab.3 shows that regression has significant with all variables at 95 percent, and talks to us that our "*model 1*" is available to explain 19.6 percent varies OCA\_UWA by IEX, LC and Leverage. R-squared of *model 1* is the general affect of all three variables, and these variables are not same significance level. Although they have regression coefficients but

regression coefficients of each variable somehow depend on stand error and its variance. From here, I employ one more method name's LMG to take consultancy about the significance level of dependent variables in "model 1". This method has been developed and proposed by Lidermann, Merenda and Gold (1980). LMG metric the important related of each dependent variables in model by computing the average contribution of R-square from each variable as its importance in model. In this case, our model take consult from LMG is *model 1*. Result is shown on Tab.5. Consultancy from Tab.5 advices I focus on which variables will be considered in next step.

- ***Causation test***

To corroborate our second aim, I conduct Granger – causation test. I expect null hypothesis rejection which would support findings of variables in *model 1* are causality one another, our initial idea to provide further insight for next period.

Before going to run Granger – Causation test, I first tested the stationary of variables to make sure the data into Granger – Causation test could not make false positive test and may give right result as well. The Ljung-Box test was performed to test their stationarity. In all tests, I am received that all data which are represented by the variables are not stationary. If input this form of these data into Granger test, we may take of false positive result. Hence, I transformed all with first-order difference and then checked again if they were stationary or not. Then, the results are shown by Tab.6, after transform at first-order difference, all variables are become stationary.

The form of models in Granger – Causation test is:

$$\begin{aligned}
 Y_{it} &= \sum_{i=1}^n \alpha_i Y_{t-i} + \sum_{i=1}^n \beta_i X_{t-i} + u_{mt} \\
 Y_{it} &= \sum_{i=1}^n \alpha_i Y_{t-i}
 \end{aligned}
 \tag{2}$$

Where  $Y$  at first test is dependent variable,  $X$  is independent variable, at first it is ST.LC.

$i(1,n)$ ,  $n = 3$ .  $n$  is the lag for this test. After lag = 3,  $Y$  and  $X$  change position together. And this process be repeated second time with the replacement of ST.IEX for ST.LC

$m$  is the time of  $Y$  and  $X$  changed or  $X$  be replaced,  $m(1,4)$ .

Hypothesis: the null hypothesis for this test is of no causality from independent variable to dependent variable.

I repeated a similar test of Berger in 1994 to verify my second aim, I conducted Granger-Causation test with OCA\_UWA, LC and IEX (Berger, & Udell, 1994). Leverage has a good trend already and I abort Granger – causation test with this variable. I expect  $H_0$  rejection, which would support my initial idea about the causality of these variables. My data was not perfect and some other environmental factors were ignored. Therefore, I had to relax some assumptions related to the linear regression: Capital market is perfect in the period of model, shareholder maximizing behaviour, no bankruptcy costs, no barriers to entry, no taxes and deposit insurance changed, nonnegative amounts of equity and debt are chosen at the beginning of the period. Bank management has no private information, so debt and inventory are symmetrically informed with management about bank investment payoffs.

The null hypothesis of Granger tests are changed as the variables are tested if they cause forward and backward each other. And the alternative hypothesis are opposite for each cases.

These hypotheses are showed together with Tab.7. And before Granger test, I do the test of stationary of data as show in Tab.6.

## **4 RESULTS AND DISCUSSIONS**

### **4.1 The trend of indicators**

#### *a. Own capital*

The variance of Tier 2 may be explained by two main reasons. Firstly, during period from 2000 to 2005, thanks to good economic situation, growth rate of banks was very high. In 2006, SBV issued the prudential ratio regulation, which required minimum capital for all commercial banks. So, banks' own capital including Tier1 and Tier2 had been increased sharply as it was shown in *Fig.2* and *Fig.3*. Secondly, some empirical studies found that when banks were required to increase their capital, initially, banks tend to raise its Tier 2 capital with Tier 1 adjusting subsequently (see Aggarwal & Jacques 1997). But as the regulation, in the Basel framework and circular No. 13/2010 of SBV, if a bank fails Tier 1, it automatically fails the total requirement as the regulator impose that Tier 2 cannot exceed 50% of Tier 1. The requirements on minimum capital of banks forced banks to consider either to increase their capital or to merge with other bank so as to achieve such minimum capital in the beginning of 2011. There were two M&A transactions taken by 05 Vietnamese commercial banks during that period. The main reason is capital while the same difficult stage of the Vietnamese stock market.

Because the total capital and tier1 were being increased while tier2 was being decreased, this trend had effected to the lessened of OCA\_UWA. In Rime (1998) and some articles published before, studies look at the effects of lagged capital ratios on banks' long-run targets for the ratio of risk-weighted to total assets, and such substitution, rather than being a response to binding capital requirements, might reflect the efforts of financially troubled banks to rebuild capital structure.

#### *b. Leverage, expenditure and ROE.*

As the charts shown, we see that although leverage in *Fig.6* is variations in the whole the period but the decrease from 2010 is a good signal, all the indicators had been growing during two third of the period from 2003 to 2010 but then after 2010 tier2, OCA\_UWA and ROE had been going down. The decrease of leverage (Leverage) is a good signal. The lower leverage the lower risk too. A rising sharply gives risk-weight capital ratio a stable and seemingly strong (see Bordeleau, 2010).

While p-value from permutation test (show in Tab.2) of both leverage (LC) and return on equity (ROE) are not significant but leverage is near to the threshold of ninety percent significance. Expenditure for interest (IEX) has a highest change in the 2008 to 2013. This manifestation may be understood that while strengthen the capital, banks were costs much more than before as the finding of Apanard (2009). In the study of Allen, et al (2012), authors argued that when had been cost higher than before, banks had been being cost the borrower, but when the economic going down banks can not do it.

In 2009, Leverage level was sharply down, while expenditure increased. These were simply as the result of some empirical studies had evidences that a high leverage of banks' capital tend banks to high profit (or opposite) and increase (or decrease) risk as less liquidity (Gorton & Winton, 2000). Or addition capital requirements but constraint on institutions with substantial exposure (low risk weight assets), bank will reject to hold traded securities or mortgage lending higher risk-base capital standards (Aggarwal & Jacques, 1997), the result that it effect narrower loans to customer of banks but LC in *Fig.7* is shown that this indicator

has been growing up along period. Then in 2010, Leverage had been turn up and kept smooth variance till 2011 before down again during 2012 and 2013 simply as the trends of IEX, DC and ROE in period. The changing during 2011 to 2013 was not quite same as its in last period especially trend of leverage and expenditure.

**Summaries the trends:** During 2003 to 2013, Vietnamese commercial banks have strengthened their capital. Although there are some indicate trend of the transformation has been more tend to the capital requirements of The Central Bank, and reflects the change from 2007 has been more following up to the trend of capital requirement than previous. The result of testing in Tab.2 showed that Tier1, OCA\_UWA, LC, TA, IEX in period 2008 to 2013 have been changed more significantly than before and this provided more consolidation in explanation for the trend of these indicators.

Approximative 2-Sample Permutation Test data: x by as.factor(y) (2013, 2007)			
Indicator (Variable)	Z value	p-value	Changing Signification
Tier1	-4.5988	0.0000	Yes
Tier2	-4.0907	0.0000	Yes
OCA_UWA	-3.795	0.0000	Yes
Leverage	1.649	0.095	Yes(at 90%)
LC	-3.7432	0.0000	Yes
TA	-4.4874	0.0000	Yes
DC	-4.1106	0.0000	Yes
IEX	-5.1187	0.0000	Yes
ROE	1.3802	0.159	No

(R statistics language.)

Approximative 2-Sample Permutation Test had been take data from panel data of 10 banks chosen. **Null hypothesis:** that the two groups have identical probability distribution. If p-value is close to zero, the changed significantly in period 2008 to 2013 is significant in compare with the changed of 2003 to 2007 period.

**Alternative hypothesis:** the change is not significant between these periods. Permutation test method has an advantage that it tests for both parameters and non-parameters in compare between two groups or periods.

## 4.2 Relationship of variables

To answer for the second main point of our study, I employed a regression model. From indicators in Tab.1, I decided to place OCA\_UWA as dependence variable. Intension of OCA\_UWA included own capital and total assets (unweight-assets). So I predicted that if this variable could be improved, it means the capital should be improved in general.

While OCA\_UWA is dependence variable, I do not use Tier1, Tier2 and TA because they are absolutely relate with OCA\_UWA and the occurrence of them in model will lessen the estimation efficiency of other variable in model. Thus, the output of BMA method, I have ROE, IEX, LC and Leverage as the independent variables in my model. *Model 1* may explain 19.56 percent variation of OCA\_UWA Tab.3.

Tab.3 – Result of BMA method. Source: Take data from data of 10 selected Vietnamese commercial banks, calculated by author.

	p≠0	EV	SD	model 1	model 2	model 3	model 4
OCA_UWA	100	1.314e-01	2.189e-02	1.475e-01	1.125e-01	1.376e-01	1.015e-01
ROE	35.7	3.999e-04	6.571e-04	--	--	1.218e-03	5.607e-04
IEX	100	-6.096e-09	1.523e-09	-6.002e-09	-6.056e-09	-6.229e-09	-6.170e-09

post prob		--	--	0.338	0.306	0.304	0.052

*(R statistics language. BMA method.)*

Result of permutation test (*tab.2*) for Leverage is not good as the other but leverage is an important indicator of Basel core so I keep this variable and abort DC variable because DC absolutely relate with Leverage.

Back to the trend of indicates we have from charts, LC and IEX are two indicators which keep going up all the period. But the figures are shown in Tab.4 that both LC and IEX are negative with OCA\_UWA and Tab.5 consult that LC and IEX are respectively the most importance variable and the second importance variable in *model 1*. Thus, these variables would better reduced rather than increased. But in this case, the time to improve capital of Vietnamese commercial banks occurred right into economic recession effected worldwide, so banks could not pass on the increased costs to their borrowers, this situation explains why ROE falls sharply and IEX increases during the same period.

(R statistics language.)

When requirement for banks' capital has been enforced, to addition capital requirements but constraint on institutions with substantial exposure (low risk weight assets), bank will reject to hold traded securities or mortgaged lending (Aggarwal & Jacques, 1997). In Vietnam, all most banks loans are mortgaged ones and together with a poor and illiquidity market of bond, do not give them more choices as the finding of Malloy (2008).

On the other hand, economic downturn coupled with high inflation at around ten percent during 2008 - 2013 made people stop exposure to other investments but rather focus on bank deposits, as shown in Fig.10. The decreasing of ROE from 2010 to 2013 although expenditure for interest has been turned down from 2011. So, the gap of interest for loans of Vietnamese commercial banks this period is come narrower than before and the downturn is shown in Fig.11 of RI in 2011 as evidences about this situation.

Calculating from data of all Vietnamese commercial banks the ratio of turnover from interest of loans out on total turnover I take figure is 89.5 percent. It means that all most revenue of Vietnamese commercial banks comes from banks' assets (or lending out).

Study of Bordeleau (2009) found that Canadian banks did not have non performing loans during the downturn as other countries did due to a constraint of leverage level. Additionally, the negative correlation between OCA\_UWA and LC shown in Tab.4 suggested that a reduced of LC contributes for an increased of OCA\_UWA. Thus the decrease reflects of Leverage in Fig.6 is a good trend of this indicate and may help OCA\_UWA to be improved. A decreased of LC or Leverage or IEX to improve expected OCA\_UWA. In this case, the finding of Belas, et al (2012) about approaching method with collateral ratios, resulting capital requirement would be much usage. Own methodology for credit risk measurement can bring substantial saving on equity through which the bank can accelerate their performance to minimization effect in relation to impacts of new banking regulation (See Cipovova, E., & Belas, J., 2012).

Trial calculation following SBV's guidance with an assumption that all these 10 banks would apply the calculation as guidance of the Central Bank. Ratio of CAR<sub>try</sub> in end 2013 is 6.81 percent (OCA\_UWA in the end 2013 is 10.54 percent). Compare with figures from empirical data, I may estimate that if IEX wouldn't be increased, Leverage will be kept the down trend as two recent years and LC will be cut down same as 2010 level, 10 Vietnamese commercial banks may perform as the CAR benchmark of SBV (9 percent) in a short time after 2013.

### **4.3 Granger causation and next period**

It is too interesting that IEX and LC are caused by OCA\_UWA include IEX and OCA\_UWA are bilateral causality. The causal relationship is occurred within two lags of Granger test model. Tab.7 provides a prediction of econometric methodology for trend of OCA\_UWA. After OCA\_UWA has changed for two years, LC will be changed, and the changing of IEX and OCA\_UWA causal each other. Connecting this point with the fact of charts graphic may explain why the chart of LC would not be going down while the economy has been being down and similar trends of OCA\_UWA together with IEX.

As the gap of loans interest is come thinner, pressure on interest rates on deposits will affect deposit volume. Both banks' assets and liabilities would decrease in the next period and then expenditure of bank for interest would decrease as well.

The expectation to reduce LC and IEX will make OCA\_UWA promptly become better, after two years it may affect to LC and IEX and improve the profitability of bank. When bank is changing toward higher capital regulation required the loans out would be cutting down and this process itself subsequently may make profitability of bank dropped (Allen, et al, 2012). Notably, at the same time, bank is safer and more stable. Higher capital regulation and stable of bank are positive with bank's profitability (See Chien-Chiang Lee and Meng-Fen Hsieh, 2013 and Ephraim Clark, et al, 2014). And greater capital regulation stringency exerts marginally positive effects on bank efficiency (Barth, 2013). In this case I find that the improvement for LC, IEX and some other relative indicators is two year lag.

(R statistics language. Granger – Cause test. Formular (2))

**Summary:** All variables in *model 1* are negative correlation with OCA\_UWA two of which have been moving toward opposite direction for efficient to OCA\_UWA from 2007 to 2013. They are not conducive for the next period in general. Vietnamese commercial banks may meet the benchmark issued by SBV if they could control loans to customer as the level of 2010.

Granger – causation showed that within 2 lag an improvement of OCA\_UWA of Vietnamese commercial banks going to cause LC and IEX. In case the control of OCA\_UWA is positive, this fact will make the regulatory of Vietnamese commercial banks be better after 03 years adjusted of OCA\_UWA.

## 5 CONCLUSIONS

After issuing requirement of capital regulation, SBV selected 10 commercial banks from 40 Vietnamese commercial banks to applying more regulatory capital of Basel. Our analysis from data of 10 selected banks from 2003 to 2013 could answer two questions.

First: As discussion in charts, result from Tab.2 about the trend of variation of capital indicates in 2003 - 2013 period. To have the answer, I employ the permutation test from data separated to two periods, one from 2003 to 2007 when regulation was not effective and the other one from 2008 to 2013 when regulation is compulsory. The result and analysis may come up with the first conclusion: in second half of 2003 – 2013 period, the ten selected commercial banks of Vietnam is tend to positive significant with more capital regulation.

Second: Employing BMA methodology to select best model from some model having same variables group, and taking the consult from LMG regression method to measure the important level of variable in model, I recognized that loans to customer, expenditure of banks for interest and leverage have negative relationship with the capital structure beside some indicators which have direct relationship with capital as tier1, tier2. But at this time, loans to customer and expenditure of banks for interest are still high. I propose that banks should consider to control their loans to have a better profit when improving capital structure.

Following these consultancies, and last, I tested Granger – causation to provide a more information that after control and adjust for capital structure (as OCA\_UWA in this article) in some lags, this adjustment may cause to loans out and expenditure of bank.

In one hand, regulation of Basel and SBV mentioned more regulatory criterions than my study. In the other hand, Vietnamese commercial banks were not fully applied or simultaneously enforcement of the circulars of The Central Bank. Thus, the models, tests and analyses mostly were based on assumptions. Management, strategy, environment variables and other fluctuations were not taken into model. Moreover, data of small group of Vietnamese banks are not the representation for the whole banking industry and so on. These are the limitations in my study.

Time for applying Basel largely to Vietnamese commercial banks is expected in the end of 2018. More empirical study in the coming time may provide more evidence for the performance Basel in Vietnam. . So, data from next time would give clearer picture than this study. My findings and recommendation in this study are regarding to loan out of Vietnamese banks. So, our next study would be address about the regulation impact on this activity and their interactive.

## **SUBSAMPLE ANALYSIS IN STRUCTURAL EQUATION MODELLING EXAMPLE FROM CUSTOMER SATISFACTION MODELLING IN BANKING INDUSTRY**

*Lubor Homolka, Jaroslav Belás, Jiří Doležal*

### **Abstract**

This paper stresses the importance of sub-sample analysis in the context of Structural Equation Modelling. Based on original survey on 459 banking customers, structural model of latent variables pricing policy, individual approach to customer and customer satisfaction was investigated with respect to sex groups. We've found that pattern of *females'* answers is inconsistent with economic theory-driven expectations and differ a lot from answers obtained from male subsample. Combining both subsets resulted in expected behaviour pattern –this was the problem we've decided to analyse. We show that although overall model exhibit good fit characteristics, results cannot be generalised on both sexes. This is because of different values of estimated coefficients and their corresponding standard errors on subgroups.

*Keywords: customer satisfaction, Structural Equation Modelling, factor analysis, sub-sample analysis*

JEL Classification: C18, M39

### **1 INTRODUCTION**

Understanding to customers' needs is crucial for successful business endeavour. This kind of knowledge is necessary condition for establishing customer satisfaction and loyalty. Customer satisfaction is a topic which received a lot of attention in the literature. Thomas (2013) summarises findings on determinants of customer satisfaction in retail industry and also finds that the association between satisfaction and repurchase-behaviour is positive and strong. Also, satisfied clients are more likely to spread positive information about products and prices. Wang, Zhao, Wang & Liu, J. (2007) review research on relation between satisfaction and loyalty. They list important papers which demonstrate that satisfaction positively affects loyalty. They claim that loyal customers are source of the stable profits because they are less cost sensitive, re-purchase more and transaction costs diminish faster than in group of not-loyal customers. They conclude that satisfaction influences financial performance through loyalty. But, they also point to "satisfaction trap" described in Jones and Sasser (1995) which states, that satisfaction itself does not guarantee loyalty. Modelling satisfaction is therefore important for understanding present state, but also for prediction of business development.

Recent development in retail banking industry introduced type of banks with non-personal customer relationship management. Trust and loyalty is built on the quality of financial products rather than on personal communication with bank officer or on other supplementary services. For such banks proper understanding of customer segments is of the highest importance.

This paper points to the problem of inconsistent results which can occur on different sub-samples of the overall dataset. Our premise states that aggregated results can be considered as valid and useful for further inferences only when estimated characteristics can be found in sub-samples, such as nationality, sex or education level. Belás, Cipovová, E., & Demjan (2014) found significant differences in all of these factors. For this paper we have selected

sub-class analysis on sex. In the questionnaire survey respondents were asked about their sex (male/female). This is biological perspective (sex) which differs from gender concept, which is social-psychological. It is expected, however, that this difference in meaning does not significantly affect the results and therefore next discussion on gender is relevant. In the research review article written by Meyers-Levy and Loken (2014) authors analyse differences in gender with relation to cognitive processing style, responsiveness and reactions on marketing stimuli. They point to the three streams of theoretical approaches which might identify such a difference. Social-cultural approach highlight inherent capabilities (physical size of individuals of group) resulted in different roles in the society. Evolutionary approach is concerned about the process which resulted in roles we witness today. Hormone and brain science "enhances the plausibility" (Meyers-Levy and Loken, 2014) of the previous two approaches. All of these perspectives can explain different customer behaviour, which were found in retail banking research (Belás, Holec, Homolka, 2013) or activity-travel research (Ren, 2009). Ren provides references on specific consumer behaviour with respect to gender. He concludes that gender is often treated as an exogenous variable and its role in estimating causal structure is not considered. Meyers-Levy and Loken (2014) confirm this by stating that "... gender has been treated as an interesting moderating variable and less as a subject of theoretical inquiry".

The aim of this paper is to address the problems which might be present but are hidden to the researcher when the analysis is made only on the top level of aggregation. The paper is organised as follows. In the methods section we present descriptive statistics of the sample and list methods used for assessing reliability and validity of measurement model of Structural Equation Model (SEM). Result section is divided into two chapters. First presents results obtained from the overall sample. In the second chapter we discuss results and its differences for two sexes obtained on respective subsamples.

## **2 METHODS**

Our convenience sample of 459 respondents consisted of 258 females. For 245 respondents the highest education level was high school. 202 respondents hold university degree. These proportions do not mimic educational situation in Czech Republic as the proportion of university degree holders is around 30 % in group of 30-34 years.

Original questionnaire was designed to address more dimensions than 3 selected for this paper. Questions were constructed by experts in the field of banking to govern face validity of questions.

Internal consistency of the indicators (item reliability) was assessed by Cronbach ALPHA coefficient with corresponding standard error. Discriminant validity requires indicators to load on latent construct which they are supposed to measure. Principal Component Analysis (PCA) or Exploratory Factor Analysis (EFA) are two main approaches which are being used to check whether the constructs exhibit discriminatory power. As opposed to Confirmatory Factor Analysis (CFA) these analysis do not know in advance which indicators should, according to economic theory, group together. In case of PCA even the number of latent constructs is not known. We use EFA because we are more concerned about the latent variables than about dimensionality reduction which is primary purpose of PCA. Oblimin (oblique-type) factor rotation was used because we expect latent constructs to be correlated. Criteria for confirming discriminatory power amongst factors were: 1) individual loading is close to 0.4 or higher, 2) cross loading is considered if the second highest loading is close to 0.3 or higher and the difference between loadings is smaller than 0.1. We have iteratively updated our model by removing/adding variables with high cross-loadings and low

communalities. Communality is a proportion of the shared variance of the indicator with the factors. Low communality indicates that the question is perceived as unique and therefore irrelevant to other questions.

Appropriateness of data was checked by performing Bartlett's Sphericity test of correlation matrix. Kaiser-Mayer-Olkin statistics of sampling adequacy was performed, too.

SEM model was estimated using R package lavaan (Rosseel, 2012). Additional absolute fit statistics, root mean square error of approximation (RMSEA) and standardised root mean square residual (SRMR) were computed. Comparative fit measure (Comparative fit index - CFI) shows how the model changed by user specification when compared to the full baseline model. Usually the value above 0.9 is considered as good fit (Hair, 2013).

In the first step EFA was employed and corresponding characteristics described above were computed. Analysis on sex sub-samples follows.

### 3 RESULTS

We start our analysis on full data set. In the following chapter differences between sexes are discussed.

#### 3.1 Analysis without subsetting by sex

Results of EFA on the overall set without stratification revealed that the most important dimension (on overall) is pricing policy. This dimension accounts for 40 % of explained variance. Factor analysis identified 48 % of all variance if the data (displayed in Tab. 1). Indicator with the lowest communality was sat2 ("I inform people around about the satisfaction with my bank."). This statement might not have been understood as the others because it does not directly speak about satisfaction development but rather about sharing experience and satisfaction. Because this indicator has high cross-loadings it was dropped from the further analysis of overall results. The second most important dimension was satisfaction. All corresponding satisfaction indicators load as expected and their cross-loadings are small.

Tab. 1 – Results from EFA. First column contains names of indicators. In the next three columns factor loadings are displayed. Column Com contains value of indicator's communality. Last column is estimated Cronbach  $\alpha$  and corresponding standard error in brackets. Last row presents values of variance which is explained by corresponding factor. Variable with low communality is being usually eliminated from the data-set, because the factor loadings are small. Source: Own processing.

Variance (%)    40    34    26    Total variance 48%

Question *inap2* ("My bank accommodates my specific needs.") was initially intended to gauge individual approach to client. Because of the correlated nature of the studied variables and their content-close proximity we include this indicator into the satisfaction group. High loading and significant test of convergent validity ( $z\text{-test} < 0.01$ ) justifies this decision. Constructs' reliabilities are moderate. The lowest value is related to individual approach and reaches values of 0.678 (standard error of the estimate is 0.026) which might be considered high with respect to the large sample size.

From the Fig. 1 we can read standardised estimates of path coefficients. They indicate positive effect of both pricing policies (*prp*) and individual approach (*inp*) on satisfaction (*sat*). On the overall sample the effect of pricing policies is stronger than individual approach. Both estimates are statistically significant ( $p\text{-val} < 0.01$ ).

Bartlett test of sphericity rejected null hypothesis ( $\chi^2 = 51.176$ ,  $p\text{-val} < 0.01$ ) about absence of correlations between constructs. KMO index equals 0.58 and MSA for each item are 0.58, 0.55 and 0.65 for pricing policy, satisfaction and individual approach respectively. These values are close to the minimum recommended value 0.6.

In the next step SEM model was fitted. Overall fit statistics indicate acceptable fit with CFI = 0.908. 90 percent confidence interval of root mean square error ranges from 0.073 to 0.099 and standardised RMSEA = 0.069. Overall  $\chi^2$  test equals to 178.7. This indicates that observed covariance matrix is different than population matrix from the full model. This means that the model does not describe reality. Well-known problem related to this test is the sample size. The larger the study, the more inflated the test statistics. We will not therefore print this statistics further as it will result in significant results due to the sample size.

Fig. 1 – Structural model presents type of relation (double-headed arrow indicates covariance whereas single arrow directional relation). Price policy (*prp*) exhibit stronger influence on Satisfaction (*sat*) than Individual approach (*inp*). Source: Own processing.

### 3.2 Analysis on subsamples

In the next step analysis on both levels of sex was performed. Factor analysis results obtained from male subset revealed that two constructs, price policy and satisfaction have similar importance in describing the variance. Indicator with the smallest communality and factor loadings is sat2 (and therefore was removed from male subset). Indicator inap2 exhibited large values of cross-loadings in initial model (0.41 on satisfaction factor and 0.37 on individual approach). This indicates that this indicator cannot be considered as a sole measure of individual approach to customer or satisfaction and therefore was omitted from analysis. This result points to existence of intersection of perspectives. This intersection is stronger than in case of females. Female's scores achieved bigger difference; for satisfaction 0.59 and 0.31 for individual approach. But, females' results are more uncertain because two other indicators showed cross-loadings. Second was sat1 ("I'm satisfied with services bank provides me.") was considered as indicator for pricing policies (0.43) and satisfaction (0.37). Second cross-loaded question was inap3 ("I feel to be important client when I visit my bank"). This question was considered as both satisfaction (0.37) and individual approach (0.42) indicator. This (price policy and individual approach and its relation to satisfaction) seems to be the most visible difference between males and females viewpoints. Surprisingly, problematic question sat2 profiled strongly as indicator for satisfaction. After attempts of achieving loadings matrix without cross loading and composition which would reflect face validity requirement (indicators' positions in the matrix have to be in accordance with underlying economic theory) we have not able to identify clear structure. The best result is shown in Tab. 3. The most problematic is assigning *sat1* indicator to the second factor. We will continue with this assignment because it will be in accordance with our initial expectation and it is also the same results as in case of the full-set model.

Researcher is not only interested in estimated values of parameter but also about other related statistics such a standards error. Standard error of the sampling distribution of the parameter conveys information about the uncertainty about the estimate. To make this uncertainty measure scale-irrelevant we compute z-score which is a ratio of the parameter and corresponding error. Higher value of z-score indicates higher confidence about the estimated parameter. From the Tab. 4 we conclude that estimates on overall sample are the most

optimistic. Note that standard error reflects the number of observations which is here about two times higher than in sub-sample.

Tab. 4 – Comparison of path estimates. Values in brackets are z-scores which represents ratio of estimate to its standardised standard error. Note that the whole set standard values are inflated when we compare them to sub-group results. Source: Own processing.

Covariate	All sample	Male	Female
Pricing policy	0.619 (9.427)	0.587 (5.827)	0.675 (7.429)
Individual approach	0.341 (5.443)	0.340 (3.662)	0.277 (3.297)
Covariance (inap, prpo)	0.348 (4.881)	0.245 (2.426)	0.435 (4.313)

## 4 DISCUSSION

Results from the factor analysis indicates that perception of construct vary between sexes. We have not found any approach (removing indicators with cross-loadings and low communalities, change of factor-loadings rotation technique) which would yield in results which would meet conditions of both discriminant and face validity. However, we have provided solution which is in our opinion the best possible. After problematic indicators were eliminated from the analysis we have performed SEM analysis.

Results from the structural model which were obtained from the full dataset are very similar to those on sex sub-samples; in terms of path orientation and magnitude. We provide an evidence for claim that positive attitude towards pricing policy positively affect level of satisfaction. This effect is stronger than effect of positive individual approach on satisfaction (which is also statistically significant). From the uncertainty perspective full dataset results exhibit higher z-scores than those obtained on sub-samples. This would be interpreted as more certain results. This might be justified by the sample size. On the other hand this finding contradicts results obtained on sub-samples (because total set consists of two distinct-pattern subsets).

This paper pointed to the problem related with inconsistent data structure, which might not be obvious when the analysis is performed only on full data set. We cannot consider statements about the strength of relations which were found as valid. This is because of the omitted variable problem. Originally, questionnaire was designed to capture customer behaviour and preferences on ten dimensions. This is not a flaw of the paper, because paper's aim was more methodological than inferential.

### Acknowledgments

Authors are thankful to the Internal Grant Agency of FaME TBU No. 005/IGA/FaME/2014: Optimization of parameters of the financial performance of the commercial bank, for financial support to carry out this research.

## **PLASTICS CLUSTER MEMBERS AND THEIR COMPETITORS - DEA BENCHMARKING STUDY**

*Lubor Homolka , Adriana Knápková, Drahomíra Pavelková*

### **Abstract**

This paper presents a benchmark analysis of 13 companies. Companies were selected by an expert's judgement from the sample of plastic manufacturers. These companies exhibit similar product characteristics. We propose Data Envelopment Analysis as a benchmarking tool. Nine of the selected companies are Plastics cluster members. Based on balance sheet and profit & loss statement figures from the period 2012-2013 technologic set was estimated by Variable Returns to Scale technique. Results are presented in scatter plot and described in more detail with reference to companies' peers (companies which are similar to a particular company and which highly influence efficiency estimates). Five out of six companies which constitute technology frontier are Plastics cluster members. These findings cannot be, however, considered as evidence for positive effect of cluster membership on higher efficiency. Research design is not experimental and the selected method serves only as a comparison method, not an inferential tool.

*Keywords: Data Envelopment Analysis, Benchmarking, Cluster organisation*

JEL Classification: C18, C44, G32

### **1 INTRODUCTION**

The Encyclopaedia of Management defines benchmarking (2009) as "the process through which a company measures its products, services, and practices against its competitors, or those companies recognized as leaders in its industry. Benchmarking is a management tool for determining whether the company is performing particular functions and activities efficiently, whether its costs are in line with those of competitors, and whether its internal activities and business processes need improvement." This paper was motivated by the author's research interest in companies' performances appraisal. And, additionally, by inquiry of Plastics cluster which wanted to assess and compare performance of its members and their competitors. Benchmarking is a complex process which requires various research methods and different analytical techniques. Benchmarking is concerned with the comparison of specific agents and companies. This paper addresses only quantitative parts of the process.

Results of our study have only limited implications on current economic theories as it is only an exploratory study which utilises convenient methods for multi-criteria comparisons. The goal of this paper is to identify the production frontier with respect to two inputs and two outputs and identify corresponding efficiencies for all companies. The number of inputs and outputs was selected to show the benefits of proposed Data Envelopment Analysis (DEA).

In the next section we describe and justify the selection of our data. Then, we review literature on the topic of DEA, both from the application and theoretical perspective. Then, we formalise our model and deliver results. Finally, we discuss efficiencies for cluster members and other companies. The paper concludes with limitations and suggestions for further analysis.

## 2 METHODS

This benchmark study belongs to relativist analysis, which sees reality in a time and location bound context. Findings may be transferrable to studies taking place under very similar conditions. The rubber and plastic industry plays an important role in the economic environment of the Zlínský region. According to the Czech statistical office (Statistical Yearbook of the Zlínský Region, 2014), concentration of the industry is the highest in the Czech Republic. On average, the share of plastic and rubber producers with more than 100 employees rose from 14 % in 2010 to 17.2 % in 2014. This is twice as high as the national level (8.1 % in 2013).

The most relevant companies were identified by Plastics Cluster Supervisory Board member Ing. Jaroslav Šuranský, CSc., MBA. Because of the similarity of internal processes and final products, only injection moulds manufacturers were considered in the analysis. The largest company, Greiner assistec, s.r.o. was removed from the sample because it was identified as an outlier by the technique described in Wilson (1993). Analysis was performed on data obtained from balance sheets (BS) and profit & loss statements (P&L) on netto values. Assets (BS, row 001) and inventory (BS, 032) were selected as *inputs*. These indicators were selected because they can proxy both company size (assets) and inventory strategy. Revenues from own goods and services (P&L, 05) and Ordinary income (profit / loss from ongoing operations) (P&L, 52) serve as *output* variables. Inputs were computed as a mean value of two consecutive observations because they are static variables. Both outputs are cumulative values over a year and therefore values only from the year 2013 were used.

In traditional settings several indicators are analysed both horizontally (change in time) and vertically (relative importance to base). Usually, the best companies are selected by means of expert opinion. Results observed from these companies then serve as contrasting levels to analysed companies. An alternative approach utilised in this paper, data envelopment analysis (DOE), does not rely on an expert's opinions to such a large extent. Instead of comparing single indicators (financial multiple is also considered as a single indicator although it consists of at least two indicators), frontier models aim to identify a set of maximum attainable outputs that can be produced by collection of inputs. This frontier is therefore defined on input-output space of appropriate indicators containing information about efficiency of decision making unit (DMU). Intuitive notion of efficiency states that DMU with higher outputs and with the same inputs are more efficient. When multiple inputs and outputs are considered, it might be difficult to compare the outputs as there might not be a common base (costs expressed in currency and company size measured by number of employees).

A comparison of Key Performance Indicators (KPI) among companies, which differ in size, can be difficult because of the implicit assumption of constant value on scale. This assumption is clearly violated in non-linear relations, such as the case of diminishing returns. DEA is usually performed on absolute values rather than on ratios. The rationale for this is that absolute values determine the size of DMU. Another distinguishable feature of DEA compared to other benchmarking methods is that multiple inputs and outputs are allowed to be part of the model, although they are not comparable on the same scale or unit. It is also important to point out the fact that DEA (standard model) is a non-parametric and deterministic model. There are no assumptions regarding the uncertainty of measurements that can be found in the regression analysis approach or in Stochastic Frontier Analysis (SFA).

DEA framework is versatile. It is not limited to benchmarking studies only. Network analysis which seeks to evaluate efficiencies of entities (organisation division) within the DMU is a promising application of the general DEA (multi-process) framework (Fukuyama, 2012). Samoilenko, Osei-Bryson (2013) proposed the DEA-centric Decision Support System (DEA-DSS). They also present references and a short description of ensemble methods (DEA + cluster

analysis, neural network and decision tree induction, regression analysis and others). Emrouznejad, A., Tavana, M., & Hatami-Marbini (2014) propose a fuzzy DEA (FDEA) method which might be employed in a situation where imprecise input or output variables are present. DEA was also used for bankruptcy modelling (Premachandra, Chen, Watson, 2011) and credit risk modelling Tsolas (2014).

For detailed DEA problem formulation and concept definitions we refer the reader to Cooper (2011). For solutions to common problems encountered in employing DEA (homogeneity of units and products, identification of input/output set, factor measurement and its implication on ratio or normalised data, undesirable inputs and outputs and the problem of indispensability, weight identification) see Dyson et al. (2001).

In the following section we define elements of DEA modelling and also provide some descriptive analysis of the sample.

## 2.1 Elements of DEA model and data

Technology set  $T(x, y)$  is a combination of inputs  $x$  which can produce outputs  $y$ . This technology set have to be homogenous across analysed DMUs; it also consists (implicitly) of directly unmeasurable factors, such a social or geographical condition (if this aspect brings some competitive (dis)advantage). Boundary of technical set is the set with the best performing DMUs. This boundary has to be estimated empirically. Several estimation techniques were proposed, both of parametrical and non-parametrical form. In this study we use Variable Returns to Scale (VRS) technology approach, because it relies only on two assumptions described later. Some authors prefer to use term production possibility set for the technology. There are two assumptions VRS model rely upon. Free disposability assumption states that if there is an input-output combination which constitutes technological frontier than any combination with more inputs can also produce less outputs then efficient combination and therefore belongs to technology set. Second assumption concerns convexity of frontier. That is, any mixture of efficient input-output combinations also belongs to frontier or is in technology set.

It is convenient to measure efficiency as a proportional change of inputs and outputs. Input efficiency is the smallest multiplier (change) of inputs  $x$  which allows DMU to produce  $y$ . This Farrell input efficiency is written as:

$$E(x, y) = \min(e \mid e \cdot x = y^*) \quad (1)$$

If the  $e$  is lower than 1 then DMU can produce frontier production  $y^*$  but can save  $(1 - e)$  of inputs. Value of 1 indicates that DMU is a member of technology frontier. Higher values points to the infeasible frontier production of particular DMU.

Farrell efficiency can be analysed from output perspective as:

$$F(x, y) = \max(f, x^* = f \cdot y) \quad (2)$$

Value of multiplier  $f$  then identifies how large should be the output if frontier inputs  $x^*$  would remain constant.

Authors are not unanimous on interpretation of effectiveness measures (EM). One argues that comparison is possible only when one DMU dominates the other. If this is the case, effectiveness is a measure of dominance (Bogetoft 2011). Less restrictive interpretation allows DMU comparison based on EM even in the absence of domination. Interpretation is limited to

the comparison of an analysed company to companies which constitute closest technological frontier.

### 3 RESULTS

The simplest case of the DEA model with one input and output variable can be interpreted graphically by constructing a technologic frontier in a two-dimensional plot. If more than two inputs or outputs are considered the technological frontier cannot be displayed directly. This is the case in our model. Values in Fig. 1 suggest that association between company size expressed in terms of mean asset value and total revenues is positive. Points printed in crosses and triangles define the technological frontier. Other companies are considered inefficient. Efficiency scores are printed in Tab. 1.

Tab. 1 – Table summarises Input (E) and Output (F) Efficiency for companies with company registration number (ID). Source: Own processing.

27508404	1.000	1.000	Yes				

Fig. 1 – Scatter plot of companies according to their size (Assets) and performance (Total revenue). Shape of data-point indicates both cluster organization and technological frontier membership. There is not visible frontier as the frontier was computed from two inputs and two outputs. Source: Own processing

The smallest company, which also defines the technological frontier is the company with id=27508404 (Sunplast s.r.o.). To find out which companies have similar characteristics and are therefore comparable in efficiencies, we need to look at Tab. 2. These similar companies are not directly observable in Fig. 1 because this plot shows only two of four studied variables. We will use values from Tab. 2 which reflect all variables. Tab. 3 points to peers (companies

which effect DMU's efficiency due to theirs similar characteristics of inputs and outputs) for each non-efficient DMU. Influence strength of peer is expressed as  $\lambda$ .

Comparable companies to the 27508404 (number 7) company are 9 and 12. Efficiency estimates of company 9 are more influenced by company 7 than by company 12. Company 9 reaches the value of input efficiency  $E = 0.72$  and output efficiency  $F = 1.477$  (from Tab. 1).

Tab. 2 – Column 1-13 correspond to company in row. Last column show Farrell's input efficiency. Values in table are  $\lambda$  values which point to closest DMU to DMU in row. Higher values indicate stronger influence on DMU input efficiency. Source: Own processing.

## 4 DISCUSSION

The research design adopted for this study does not allow for generalisations. This study is exploratory and descriptive and also space- and time-bounded. The sample was not selected by random. Moreover we cannot fix the factors which differentiate companies. Therefore, we do not perform a replicable experiment. Although the majority of Plastics cluster members constitute the technological frontier, we cannot claim that cluster membership makes companies more efficient. It might be the case that good companies group but the effect of being together might only be negligible.

This study is also limited by its single-period study design (although some variables are deflated by values which average two-period values). Selected technique used for estimation of technology frontier can affect the final result significantly. We have selected the VRS model because it is considered a flexible approach and only relies on two assumptions – convexity and free disposability. For the next analysis we suggest other input/output indicators, perhaps from the operational area such as the amount of material waste or energy consumption.

### Acknowledgments

The authors are thankful to the Operational Programme Education for Competitiveness co-funded by the European Social Fund (ESF) and national budget of the Czech Republic for the grant No. CZ.1.07/2.3.00/20.0147 - "Human Resources Development in the field of Measurement and Management of Companies, Clusters and Regions Performance", which

provided financial support for this research. This article has been elaborated also as one of the outcomes of research project IGA/FaME/2014/015.

## **SOCIAL RESPONSIBILITY AND ITS IMPORTANCE TO THE PERFORMANCE MANAGEMENT OF BUSINESS COMPANIES: ACTUAL SITUATION IN THE CZECH REPUBLIC**

*Jana Hornungová, Marie Pavlákova Dočekalová*

### **Abstract**

The aim of this article is to provide a framework of standards of social responsibility in the Czech Republic and mention its importance to the business management. Paper offers a literature review supplemented by the author's empiric research into the social performance. Currently the „firm's survival“ depends not only on financial competitiveness, it is equally important that the organization could demonstrate their position in relation to the various interested parties (stakeholders), which are affected by the activities of the enterprise. Based the empirical research, there is no relationship between established standard of social responsibility and profitability of company. Despite the fact of absence of this relationship, it is possible to conclude that the social responsibility in various areas is associated with many benefits for the enterprise itself. That can be a significant competitive advantage in today's rapidly changing environment.

*Keywords: social responsibility, standards, IT sector, Pearson's coefficient*

### **1 INTRODUCTION**

The concept of corporate social responsibility and its understanding, whether in relation to the stakeholders, employees, or other interest groups, in essence, from the first half of the 20<sup>th</sup> century constantly evolving. There is a gradual refinement and expansion of different definitions, but as an essential turning point may be considered the idea: "the undertaking which meets the only legislative requirements cannot be considered socially responsible." On the basis of the synthesis of individual knowledge, Carroll designed in 1979 definition of CSR, which was based on the 4 basic elements, which are, however, many believed that exclude each other. Carroll joined the area in this definition of business activities, which many believed that exclude each other. An example may be entrepreneurs who in its "economic responsibility" also gave a donation, or felt the commitments to the community, and is a typical example of Tomáš Baťa and the construction of the "business cities" (Svoboda, 2010). Businesses that do not respect the inclusion of socially responsible behavior (they are not socially responsible) into their strategies, systems and procedures, will probably remain behind the competition. Increasingly, customers, employees, stakeholders, investors, government, business partners, and the company decided to support companies which are little interested in the planet and the happy life of its inhabitants (SGS Czech Republic, 2013). To be a socially responsible company also brings benefits, among which include: reduce operating costs, increase corporate image and improve reputation, increase customer loyalty and sales (Boyd & Gessner, 2013; Blowfield & Murray, 2008).

On the timeliness issue to point out some of the research, which presents the company Bureau Veritas Czech Republic, that helps customers comply with standards and regulations relating to quality, health and safety, environmental protection and social responsibility. The company in its report "Social responsibility by standard SA 8000" from the year 2011 states that 70%

of customers prefer to socially responsible companies, every second is willing to pay more for products and services of these companies. View of social responsibility is reflected in employees, since 86% of Europeans prefer working in a solid, socially responsible company before a higher salary for the competition. CSR is a key question in business, as 85% of senior executives of transnational chains (Bureau Veritas Czech Republic, 2011).

Social responsibility should therefore be part of a corporate strategy, as expressed in the voluntary commitment of the company, contributing to a better society. Socially responsible businesses are characterized by proactive, not just reactive policy, for their leadership to actively apply new and positive trends (Boyd & Gessner, 2013).

The aim of this article is to provide a framework of standards of social responsibility in the Czech Republic and its importance to the business management. In order to achieve this aim, a critical literature review and questionnaire survey (primary research) was used. The area surveyed was Information and Communication Activities, and the focus was especially on companies in the Czech Republic with more than 250 employees.

The structure of the article is as follows. Section 2 describes the theoretical background of standards of social responsibility, section 3 presents research that explores the relationship between social responsibility and financial performance. Section 4 reveals the estimated results and the last section discusses the results (key findings) with the summary of other selected groups of standards.

## **2 STANDARDS OF SOCIAL RESPONSIBILITY**

The social area also has certain types of indicators, which can be used to measure and evaluation of performance and responsibility. For the evaluation of the social performance of the majority of non-financial indicators are used (called soft indicators). For social performance is needed to determine which of the standards will be selected social indicators. Among the ones that include in their social context, include:

- Corporate Social Responsibility (CSR);
- Social Accountability 8000 (SA8000);
- ISO 26000;
- Safe company;
- ČSN OHSAS 18001:2008 – Management of health and safety at work;
- IQNet SR 10 – Social accountability management system;
- FE – Friendly employer;
- The methodology KORP;
- Normative document – Social accountability management system.

### **2.1 Corporate Social Responsibility (CSR)**

This concept appeared in the early middle of 20<sup>th</sup> century and means a way of conducting business and building relationships with partners, which contributes to increase the credibility of the company. It's basically about the voluntary commitment of enterprises to behave responsibly in the context of its operation to the environment and the society in which they carry out its business activities. The essence of CSR is the belief that the sustainable prosperity of the company responsible and transparent way of doing business. The concept is based on the three pillars – economic, social and environmental. These pillars correspond to the three characteristics of the "triple-bottom-line" (Robins, 2008; Wood, 2010):

- Profit (economic area);
- People (social area);

- Planet (environmental area).

Behavior of an undertaking in accordance with the principles of CSR brings with it many profits, in particular, in the form of increasing the value of intangible assets such as company reputation, brand value, human capital, relationships of trust and partnership. CSR, however, can lead to cost savings, for example in connection with the low staff turnover or as a result of environmental measures. Last but not least, CSR has a positive effect on the increase in the value of the company to the shareholders (Boyd & Gessner, 2013).

According to the authors of the booklet "The concept of CSR in practice: a guide to responsible business" is the responsible behavior of the company can be divided into four areas, which expresses the following Figure 1. Alternatively, however, is the concept of CSR is divided into three areas as mentioned above.

Fig. 1 – The four areas of business responsible conduct. Source: Steinerová and Makovski (2008).

In the context of the "market environment", from the socially responsible enterprise is expected to mostly transparent business and positive relationships with investors, customers, suppliers and other business partners, taking a responsible approach to these partners leads to building mutual confidence, improving the quality of products and services and, ultimately, to achieve a higher profit in the context of trade cooperation. The inclusion of CSR concept into the corporate strategy is considered a sign of good management in the enterprise. From the point of view of the market is also watching the impact of the business on the economy, for example in the form of employment, infrastructure development and the fight against corruption. At the same time, it is possible to identify the benefits that are related to responsible behavior in the market environment and ranks among them mostly: customer loyalty, differentiate from the competition, the desired vendor and business partner, increasing the efficiency of the supply chain (Milichovský, 2013; Steinerová & Makovski, 2008).

In the area of "working environment" are the most important component of the staff who are dependent on the enterprise considerably, not only financially, but also "human", as in the work of the day and spend a significant portion of carried out activity affects the quality of their private and family life, often has an impact on their health. On the other hand, the long-term success of the company depends on the quality of its employees, who are an essential part in achieving the goals. With responsible behaviors in the work environment are associated certain benefits, which can be defined as follows: desired employer, quality employees, motivation, productivity, leading to a creative and innovative environment and low staff turnover.

As far as the "local community", only for explanation, it should be noted that, at the commencement of the business activities of the company becomes part of the surrounding

community. Socially responsible enterprise develops efforts to establish good "neighborly" relations (e.g., its negative impacts mitigated). A specific form of support can be financial or material support of public activities and projects. The firm, which has been actively involved in the local community, can identify new markets and business opportunities, build contacts with local authorities, to attract the attention of the media and also makes it easier to establish new partnerships with other enterprises. Also in support of these activities, it is possible to count with certain benefits, which may be: the good name of the undertaking, customer loyalty, employee loyalty, access to local resources, a new business opportunity, etc. (Steinerová & Makovski, 2008).

Also in the area of the "environment", the company, which is trying to minimize its impact on the environment, this may be an effort to bring new business opportunities. Active in the environmental field has the option to bid on tenders of large corporations and public administration or to obtain new customers from among environmentally conscious consumers. An eco-friendly way of doing business also brings financial savings. Environmentally friendly energy use, pollution prevention, minimization of waste and recycling, all this can bring to the company more efficient operations, a significant reduction in costs and other benefits (Steinerová & Makovski, 2008).

## **2.2 Social Accountability 8000 (SA8000)**

SA 8000 is an international reference standard for the improvement of working conditions, which may be regarded as the basic standard for the certification of conformity with the requirements on corporate social responsibility, which is globally recognized as the reference standard for social responsibility. This is the standard by which they are carried out by independent third party audits. This standard is generally applicable to any sector, the scope of business activities and for a company of any size (Ciliberti et al., 2011; Bureau Veritas Czech Republic, 2011). Businesses can convince and prove a measurable way to its business partners the results of corporate social responsibility in their business. Significantly improve your position so in a competitive environment. Gilbert and Rasche (2007) evaluating the standard SA 8000 as a very high beam assist, not only for businesses but also for all interested parties, since they help to communicate effectively on issues of social responsibility.

## **2.3 ISO 26000**

This standard was published at the end of 2010. The aims of introduction of ISO 26000 are: to increase the competitiveness of the enterprise; increase the reputation of the company and strengthen confidence; improve the relationship business to interested parties; increase loyalty, engagement, participation and morale of staff; increase the safety and health of workers; the creation of innovation, improve the procedures for risk management in the organization; increase the reliability and correctness of transactions; the prevention or reduction of potential conflicts with customers, etc. (Jacobsen, 2011). On the basis of this standard it is possible to completely assess the performance of the company and at the same time increase the level of responsible behavior (SGS Czech Republic, 2013). In July 2011, this standard was introduced as the Czech technical standard ČSN ISO 26000: 2011 (Kašparová & Kunz, 2013; Národní politika kvality [NPK], 2011; Henriques, 2010).

## **2.4 Safe company**

The program "safe company", which is called by the Ministry of labor and Social Affairs of the Czech Republic and the State Labour Inspection Office, allows to employers implementation of OSH management system which corresponds to the Czech legislation, but also the requirements applicable in EU countries. Currently belongs to the most recognized

documents in the area of OCCUPATIONAL SAFETY and HEALTH in Europe, document OHSAS 18001 and ILO-OSH 2001 and just program the "safe company" comes from these documents. The aim of this program is to increase the level of safety and health at work, including the protection of the environment, to achieve this higher level of culture at work and well-being and create the conditions for the introduction of the integrated management system (Státní úřad inspekce práce [SÚIP], 2009).

## **2.5 ČSN OHSAS 18001:2008 – Management of health and safety at work**

Standard OHSAS 18001 has been designed to be applicable for businesses of all types and sizes and builds its structure to the standard ČSN EN ISO 9001 and ČSN EN ISO 14001, to create a management system for safety and health at work in parallel with the quality management system and environmental management system. Application of OHSAS 18001 is based on risk analysis and their minimization. The main purpose of the application of the standard is to lead companies to propose and implement measures that will reduce the danger of removing, or employee from him isolated. In the event that it is not possible work must be planned and controlled by organizational measures so that its performance will be safe and not to endanger the health (Association for the Certification of Quality Systems [ACQS], 2010).

## **2.6 IQNet SR 10 – Social accountability management system**

The main requirement of this standard is that the organization has identified all its impacts arising from their decisions and actions. These impacts must evaluate, and that with regard to the stakeholders and to sustainable development. An important part of this standard is to identify the requirements, expectations and needs of stakeholders. The company, on the basis of the obtained information, establishes goals, target values and programs. In their compilation takes account of the involved parties, but also on its technological options, financial, operational and business requirements. The company must determine what is the perception of stakeholders, i.e., if their expectations and needs were filled (Association for the Certification of Quality Systems [ACQS], 2010).

## **2.7 FE – Friendly employer**

The Association for the certification of quality systems, together with the Association of TRIANON Bohemia work together to create and promote new certification marks FRIENDLY EMPLOYER. This label is awarded to organizations or individuals in recognition of the long-term capability and accordingly to include people with disabilities into the workforce and continuously develop their skills and qualifications. This certification mark meets one of the pillars of corporate social responsibility. Its main concern is the confirmation of the purity and transparency in the implementation of Act No. 435/2004 Sb., on employment and anti-discrimination Act No. 198/2009 Sb. The company which, thanks to the rules creates an environment for peaceful and safe involvement of workers with reduced working ability should be properly visualized and awarded (Association for the Certification of Quality Systems [ACQS], 2010).

## **2.8 The methodology KORP**

This is a purely Czech standard, which is used in particular as the basis for the evaluation of enterprises for the purposes of "CZECH national awards for social responsibility of organizations", but it is also usable as a self-assessment tool for organizations. This is a set of criteria and sub-criteria that are divided into three pillars of corporate social responsibility. The methodology focuses on the evaluation of the results, both in the field and in the area of

assumptions, where is applied the cycle PDCA. It is possible to evaluate the ability of the organization in achieving positive results in the area of corporate social responsibility in the long term (Krohová, 2009).

## **2.9 Normative document – Social accountability management system**

On the basis of the demand of the business sector after the certification standard for the area of corporate social responsibility of organizations within the framework of the National policy of quality in 2011 created a normative document titled "social responsibility management system". The requirements of this document are in accordance with the requirements of other management systems standards (in particular, the standards ISO 9001 and ISO 14001), and thus facilitate its application in organizations that have any of these management systems are introduced. However, the document may be used by any organization as a basis for the introduction of the concept of the social responsibility of organizations across the breadth of the three basic pillars, including the creation of the necessary conditions for the maintenance and continual improvement of the system of management of corporate social responsibility (Národní politika kvality [NPK], 2011).

## **2.10 ČSN 01 0391 – The management system of social responsibility of organizations**

The standard advocates CSR principles in the context of management systems. It includes requirements for social responsibility pillars (economic, environmental and social) management system requirements and the requirement for continuous improvement in accordance with the PDCA cycle (Plan - Do - Check - Act). It creates a space not only for certification, but also for integration with other management systems standards (quality, environment, etc.). It is applicable to organizations of any size and type of business and public sector (Empress, 2013).

# **3 CORPORATE SOCIAL RESPONSIBILITY AND CORPORATE FINANCIAL PERFORMANCE**

In fact, since the beginning of the emergence of the concept of CSR exist in both its supporters and opponents, who are presenting their belief in the correctness of their opinion. Many experts began to focus on the empirical impact of CSR on its economic and financial performance. However, it should to add that to this day has not been achieved by any general scientific consensus on this issue and the views of many groups of experts and scientists are quite different.

One of the first studies with the impact of CSR on economic performance is the work of Milton Moskowitz from the year 1972. Author of 67 companies selected the 14 best in terms of the level of CSR and calculated the average growth in value of their shares. The result was the average appreciation of 7.28% while the Dow-Jones Industrial exhibited a value slightly lower. This result was considered to confirming the hypothesis that CSR has a positive impact on the economic performance of the company (Moskowitz, 1972; Kukačka, 2008).

Heinz (1976) used the correlation analysis of ROE, ROA and margins and in this case showed a positive correlation between CSR and ROE. Cochran and Wood (1984) have used in their work several financial indicators, and their conclusion is that the strongest correlation exists between CSR and age of corporate assets, i.e. enterprises with legacy assets reach lower valuation in terms of social responsibility.

Guerard (1997) examined the impact of CSR on the share price of companies in the course of eight years and found that there was no difference between the average stock returns socially

responsible and irresponsible businesses. McWilliams and Siegel (2000) in their econometric study concluded that CSR has no impact on the financial performance of companies. Regarding the relationship between CSR and CFP (corporate financial performances several studies have found that CSR impacts CFP positively (Bird et al., 2007; Nicolau, 2008). Inoue and Lee (2011) did not find any significant effect of CSR both on ROA and Tobin's q across three different dimensions of CSR. In another recent empirical study, Barnett and Salomon (2006) examined 61 mutual funds that apply social responsibility screens and found a curvilinear relationship between social investment and financial performance. They further found that financial performance varied with the type of social screens; while community relations screening helped financial performance, labor and environmental relations did not, underlining the importance of considering that different kinds of socially responsible activities can have different results (Lee et al., 2013).

#### **4 METHODOLOGY AND RESEARCH RESULTS**

The basis of the empirical research was a questionnaire prepared as part of the doctoral thesis of the author. For the purposes of the author's research, businesses were selected which met the following three conditions:

- Registered economic companies from section J (CZ-NACE) – Information and Communication Activities;
- Location – the Czech Republic;
- Enterprises with > 250 employees.

A basic sample was made of 56 companies. All these businesses were addressed during the survey, 32 out of them answered (effectiveness was almost 57.14%). In terms of identification, it can be significantly statistically evaluated which types of legal form predominated: joint-stock companies (43.8%) and limited liability companies (56.3%). In the framework of the social sphere, it was first necessary to determine whether the undertakings currently pursue their social agenda, or report.

As shown in Table 1, only a small number of enterprises have introduced this type of standards. After the review of the annual reports of companies I have come to the opinion that if businesses from the selected areas have established one of the standards, it is likely to be one of the following: ISO/IEC 27001:2006 Information Security; ISO/IEC 20000-1:2006 – Management Services for Information Technology; ISO/IEC 20000-1:2012 – Management Services for Information Technology.

Tab. 1 – An overview of the use of standards of corporate social responsibility. Source: Own research.

<b>STANDARDS</b>	<b>ISO 26000</b>	<b>SA 8000</b>	<b>Safe company</b>	<b>ČSN OHSAS 18001:2008</b>	<b>IQNet SR 10</b>	<b>FE - Friendly employer</b>
<b>Introduced and used</b>	-	-	9.4%	12.5%	3.1%	-

<b>It will be implemented</b>	-	3.1%	6.3%	6.3%	9.4%	9.4%
<b>Introduction we are planning in the future</b>	68.8%	46.9%	9.4%	34.4%	9.4%	6.3%
<b>It is not significant, and therefore is not considered for the introduction</b>	25.0%	43.8%	68.8%	40.6%	71.9%	78.1%
<b>Barriers for the implementation</b>	-	-	-	-	-	-
<b>Without answers</b>	6.3%	6.3%	6.3%	6.3%	6.3%	6.3%
<b>Total</b>	<b>100%</b>	<b>100%</b>	<b>100%</b>	<b>100%</b>	<b>100%</b>	<b>100%</b>

From the table, it is clear that businesses usually don't have currently enabled one of the standards of corporate social responsibility. There it is possible to believe that one of the latest standards ISO 26000 is in effect only briefly and essentially replaced by the SA 8000, therefore its use is not up to such an extent as would be expected. It depends on whether these standard businesses will want to use in the context of its activities and within a few years will occur gradually. Proof of this is the fact that, on the basis of that research firms are considering the introduction of rather particular standards of ISO 26000, SA 8000 or the latest one ČSN 01 0391.

In relation to the calculation of the defined researches (Section 3) that examined the association between corporate social responsibility and its impact to economic area, the following *statistical hypothesis* was established:

- ***"There is an influence of corporate social responsibility (CSR) on the profitability of equity (ROE) and the profitability of assets (ROA)".***

It has been suggested that that social responsibility business has an impact on the profitability of equity and profitability of assets. In this case, was the hypothesis provided in relation to critical definition of Heinz (1976), that there is a positive correlation between CSR and ROE.

The relationship between two intervals characters is measured using a Pearson linear correlation coefficient. These characters are characterized by a long scale of measurements for this reason would be for such characters it was too desirable to create a grading table of degree II.

To verify this hypothesis was used the answer the respondents of the survey, of the question: "Do you work in the social field with one of the following standards, which are related to corporate social responsibility (CSR)?" At the same time the amount of ROE was detected and ROA by using the database Amadeus, where applicable, the data were supplemented from the annual reports of enterprises. Due to the low number of enterprises which have any of the listed standards established, the answer has been to merge: "is introduced and used" and "will be implemented." These responses have been taken as a positive answer to the question of the introduction of CSR, other than as a negative answer. To verify the statistical dependencies of the null hypothesis  $H_0$  was tested, that the random variables are independent in relation to the alternative hypothesis  $H_1$ .

- ***$H_0$ : There is no statistical relationship (link) between the CSR and referred profitability's.***
- ***$H_1$ : There is a statistical relationship (link) between the CSR and referred profitability's.***

The resulting correlation matrix has the form of a square table that contains as many rows and columns, how many variables enter into the analysis. The result of the calculation is shown in Table 2.

Tab. 2 – Pearson's coefficient of linear correlation for statistical hypothesis. Source: Own research.

		CSR	ROA	ROE
CSR	Pearson's correlation coefficient	1	-0.400	-0.363
	The significance level		0,100	0,152
ROA	Pearson's correlation coefficient	-0.400	1	0.925**
	The significance level	0,100		
ROE	Pearson's correlation coefficient	-0.363	0.925**	1
	The significance level	0.152	0.000	

\*\* Correlation is significant at the 0.01 level of significance

Pearson's linear correlation coefficient for CSR and ROA is -0.400 that exhibits a negative dependency between these two variables. The tightness of this context, however, it is average. The negative sign indicates that with the growing one variable decreases the other (in this case, the increasing number of enterprises with CSR dropping ROA).

The same incident occurred in respect of CSR and ROE, when Pearson's linear correlation coefficient achieves a negative value -0.363.

Table shows the achieved level of significance. Also in this case, the resulting value of the minimum level of significance tested at 5% level of significance ( $\alpha = 0.05$ ). If this value is less than or equal to  $\alpha = 0.05$ , negative  $H_0$ . In this case to the rejection of the  $H_1$  as the observed significance level is greater than the minimum level of significance ( $0.100 > 0.05$  and  $0.152 > 0.05$ ). Denied, therefore null hypothesis  $H_0$  at 5% significance level, meaning that between CSR and referred to profitability's there is a statistical link. CSR thus has no effect on the profitability.

To complement the above Table it is possible to observe a strong relationship between ROE and ROA, which reaches 0.925. A positive sign tells us that the ROA more grows, more grows the ROE. In this case, it is possible to interpret this statement logically and it so that both indicators are based on the calculation of the profit and therefore, if it is to increase profits, increase the value of one, so the other indicators as well. If the proposed hypothesis, which examined the influence of one of cost-effectiveness on the other, there would be in this case, to reject  $H_0$ , since the observed significance level =  $0,000 < 0.05$  and the relationship of one variable to the other would be a 5% level of significance is confirmed.

- ***Statistical hypothesis is not confirmed.***

Due to the claim therefore, Heinz is the opposite the case correlations.

## 5 DISCUSSION

Based the empirical research, there is no relationship between established standard of social responsibility and profitability of company but reason for this result may be some disclosing the value of the research. This could be increased if it is attended by more businesses. Even though the number of respondents was low enough that it is not possible to evaluate the data and formulate certain conclusions. Among the main barriers to research joined a certain reluctance of businesses in obtaining primary data. However, it is possible to say that with realization of some of the standards of corporate social responsibility, are linked several

advantages that may have a greater importance in the management of company than, for example, achieving a certain level of profitability.

It depends on the strategy of any company which takes its principles that will govern and will put the greatest emphasis. The focus at least in part on an area of CSR brings significant benefits, which lists the server [www.csrnetwork.com](http://www.csrnetwork.com), among which it is possible to define:

- **Access to capital.** Thanks to involvement in social responsibility projects, some businesses get access to capital, to which it would otherwise never get. The degree of social responsibility is taken into consideration, for example in the Dow Jones Group Sustainability Index, FTSE4Good Index, or Bit Corporate Responsibility Index. These indexes used by investors who want to learn about the CSR activities of certain companies.
- **Increase efficiency and reduce costs.** One way to reduce costs is the introduction of environmentally friendly processes and systems. At the beginning the company must spend a larger amount of money, but it will later return in the form of waste reduction, recycling and reuse of materials, less consumption of water and energy. The introduction of these systems delivers the benefits for the local community, the environment, and economic page of the organization.
- **Improve the image and the reputation of the organization.** Good reputation and confidence of stakeholders is very important for the company, but it is often difficult to achieve. One option is to care for the environment and the local community. For the enterprise, it is important to try to minimize it, but completely eliminate the possibility of environmental accidents. If any such undesirable situation occurs, it should be appropriately prepared company to learn from its and to introduce effective corrective and preventive action.
- **Sales growth and customer loyalty.** As already stated, people judge companies by their approach to the environment, corporate sponsorship or position to staff. The majority of buying customers focus primarily on price and quality, but still a greater amount takes into account other indicators.
- **The growth of productivity and quality.** Improvement of the working environment, better care of employees or employees' share of the growth in decision-making can enhance their loyalty, reduce turnover and increase the productivity of their work. Another effect may be the reduction of rejects.
- **A better opportunity to acquire and retain high-quality employees.** This point is related to the quality of the working environment, the possibility of a further deepening and improving the skills and the sharing of values, together with the management of the organization. People prefer to work for the firm, which they trust, share his views and can identify with the firm.
- **Greater leniency in the case of state authority of some misconduct.** If the company makes clear that compliance with the law is, of course, for the minimum and has activities beyond the scope of the law, can it help, for example when a request for a permit or when discussion of a particular issue.
- **Reducing the risk and the growth of risk management.** The introduction of the system of social responsibility of the enterprise can significantly contribute to reducing the commercial risk. The destruction of reputation in the media can very damage the firm in his future business dealings. Companies are increasingly trying to include it in their press releases, information on corporate social responsibility and

give their stakeholders the necessary information about the impact of the management of the company on its surroundings.

- **Increasing the competitiveness and sales.** State administration, local community and nonprofit organizations expect from companies that they will comply with all legislation and that their activity will not be too much of the burden on the environment and surroundings (Kuchtíková, 2011). Along with these benefits, or complement and extend also Weber (2008), Trnková (2004) or Kašparová and Kunz (2013).

It is therefore desirable to monitor social performance and to express its benefits for the enterprise. Social indicators should be monitored in the context of the economic result of the company and to identify deficiencies in the feedback processes, which is needed to remove (Kaplan & Norton, 2000; Porter, 1996; Kocmanová et al., 2010).

In the future there could play an important role the concept of "shared value" because increasingly, businesses are realizing that building common values can benefit both the company and increase its competitiveness. Companies can not only improve quality, quantity and cost aspects of their inputs, but can act as a driving force not only economic, but also social development. How come Bockstette and Stamp (2012), in the future will prosper especially those companies that assume and use new frontier of competitive advantage while active role in shaping the environment in which it operates, rather than just react to it. In the context of shared value is worth to mention a concept CSV (Creating Shared Values), which stems from the idea that a firm's competitiveness is naturally connected with the good of the community in which it operates. Understanding and using these links between society and the economy should lead to a new wave of economic growth (Bockstette & Stamp, 2012). Perhaps there could develop new strategic actions that would draw from this approach in the future and would be able to confirm or refute the idea of shared values to the community.

## **6 CONCLUSION**

This paper gives a comprehensive view of existing standards of social responsibility. The aim of the article was to provide a framework of these standards in the Czech Republic and its importance to the business management. Currently, more and more companies in the Czech Republic are focus on their corporate social responsibility, so the topic of the article is therefore very timely. Organizations should also consider strengthening the link (or congruence) between professional ethical standards and organizational ethics/CSR (Shafer, 2002).

On the analysis of the sample of enterprises using statistical verification has not been proven statistical link between the undertakings which have enabled one of the standards (or the introduction is already dealt with) and the values of profitability's. According to the results of the Pearson correlation coefficient was found a negative dependency between these two variables. Due to the claim therefore, Heinz is the opposite the case correlations. Despite the fact that in the absence of this relationship, it is possible to conclude that the social responsibilities in various areas is associated with many benefits for the enterprise itself. Due to the fact that the topic of corporate social responsibility in the management of enterprises starts only push interesting will be executing the same empirical research over the course of several years, so this research it is possible to consider as a starting point for further examination, which will deal with this issue. Examined all enterprises could be parsed from the area without limiting their size and individual results could be compared. At the same time could be more focused on the research of numerical data, as might be done in the period of

comparison (using time-series) and the impact of CSR on economic performance could be explored in the longer term.

Social performance, standards and indicators associated with it are an important part in the management of enterprises since they are associated with a number of advantages that can be a significant competitive advantage in today's rapidly changing environment.

## **MEASURING SUCCESS OF MERGERS AND ACQUISITIONS AND COMMON MISTAKES TO AVOID**

*Martin Hudak, Anna Neumannova*

### **Abstract**

The main objective of this paper is to provide an overview of methods and opinions on measuring success of M&A transactions being used in academic as well as in other professional spheres around the world. Setting generally accepted principles and criteria of valuation enables to determine whether a particular merger/acquisition has generated required benefit or value in accordance to the accepted set of these principles and criteria. There is no guidance or instruction book to achieve a 100% success of M&A transaction, however, there are general principles which if they are applied correctly, there is a high probability that the results, required by investors, managers and/or other stakeholders of company, will be reached.

*Keywords: measuring success, profitability of mergers and acquisitions, mistakes in M&A process, M&A success rate*

JEL classifications: G34

## **1 INTRODUCTION**

The main objective of this paper is to provide an overview of methods and opinions on measuring success of M&A transactions being used in academic as well as in other professional spheres around the world. Alongside with this objective, we explain what are the most common mistakes in an M&A process and how professionals involved in the process itself should advance in order to ensure the highest possible benefits for themselves and other stakeholders.

Diverse interests of company's stakeholders often result in different opinions and accepted decisions about the company's strategy. In general, there are several goals that most profit organizations try to achieve. The goal of maximizing shareholder value, often followed by ensuring sustainable revenue growth and generating the highest possible cash flow are among the most important ones. The latter mentioned, generating cash flows and growth alongside with return on invested capital (ROIC) relative to the cost of capital are key drivers of value creation in any profit making company. (Koller, Goedhart, and Wessels, 2010 and Marik, 2007).

A strategy of inorganic growth is often defined as a strategy on mergers and acquisitions (M&A), business combinations or simply, a strategy related to a purchase or sale of company or its business/-es. There are many methods which have been used in practice for measuring success of particular M&A transaction, however, in many cases, it is all about a subjective view of evaluator. Success is a relative term and can be defined in various ways depending on the receiver of information. Whether it is a CEO of company, an owner of company, a majority/minority shareholder or an investor investing in a particular firm or business, these all can have similar or completely opposite opinions on measuring the success of M&A transaction they are involved in. Despite this fact, setting generally accepted principles and criteria of valuation enables to determine whether a particular merger/acquisition has

generated required benefit or value in accordance to the accepted set of these principles and criteria. Therefore, it may be more correct to talk about measuring M&A performance instead of M&A success, however, for the purpose of this academic contribution, both terms are used interchangeably.

## 2 MEASURING PERFORMANCE OF M&A TRANSACTION

When we look for an answer to the question of defining successful M&A transaction, we have to take a look at the process of transaction itself and the most common failures and their causes.

Every decision on an inorganic growth starts with a strategic planning and strategic transactions as its main parts. A strategic transaction is any action that helps implement company's strategic plan. While that action can be on a small scale, such as the sale of one business unit or manufacturing plant, it can also be done on a large scale including a corporate merger with another company, building, buying and/or selling assets. A strategic action can also relate to financing, such as the decision to implement an aggressive stock buy-back program or recapitalization. According to Castillo and McAniff, the value of a strategic transaction is measured by many metrics, the most important of which is a company's stock price. A company can maximize shareholder value using both strategic transactions and financing transactions and its tools as shown in the figure below. (Castillo and McAniff, 2007, p.73)

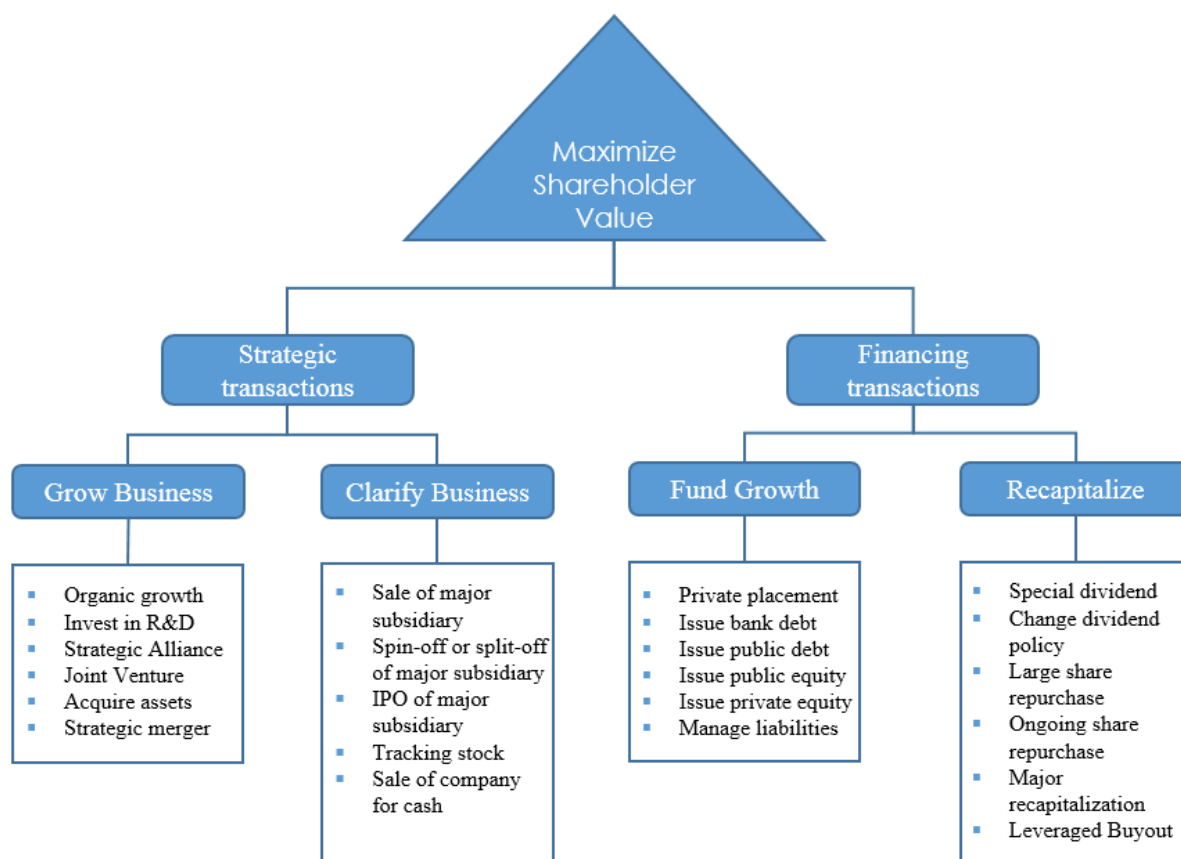

Fig.1 – Maximizing Shareholder Value. Source: Castillo, J. J., McAniff, J. P. (2007). *The Practitioner's Guide to Investment Banking, Mergers & Acquisitions, Corporate Finance*, p.74

An M&A transaction process or simply a deal process can be defined from a perspective of buyer and from a perspective of seller. Individual steps of each of the processes are depicted in detail below.

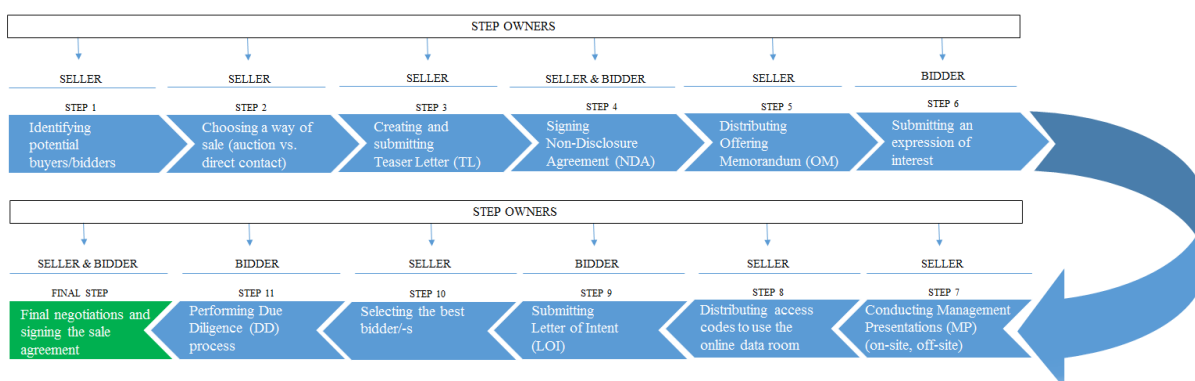

Fig.3 – Buy-Side M&A Process. Source: Author’s Research; Bragg, M. S. (2011). Mergers & Acquisitions, A Comprehensive Guide. p. 19-33; Rosenbaum, J. – Pearl, J. (2013). Investment Banking – Valuation, Leveraged Buyouts, and Mergers & Acquisitions. p. 173-192

## 2.1 Academic and professional opinions on M&A success rate

There have been many studies performed in order to identify the success rate of M&A transactions. According to Moeller, most deals do fail no matter which study you look at. The percentage ranges **from 60 to 70% for the deals that fail.** (Moeller, Max and Schiavone, 2009)

According to Grubb and Lamb, a sobering reality is that only about **20 percent of all mergers really succeed.** Most mergers typically erode shareholder wealth. The cold, hard reality is that most mergers fail to achieve any real financial returns. (Grubb and Lamb, 2000, p. 9-14)

A study on managers of acquiring companies reports that 44 % of their acquisitions do not meet their original objectives, and **about 70 % of all mergers and acquisitions are reported as failures.** (Cartwright and Schoenberg, 2006; Peng, 2013)

In addition, Cartwright reports that irrespective of the evaluation method selected, the evidence on M&A performance is consistent in suggesting that a high proportion of M&A are financially unsuccessful. US sources place **merger failure rates as high as 80%, with the evidence indicating that around half of mergers fail to meet financial expectations.** (Cartwright, 2013)

A survey and M&A success of McKinsey clients indicate that transformational value can increase the return on an acquisition from 30 up to 100 percent. Identifying transformational value opportunities and managing mergers that stretch company’s capabilities in new ways require a dramatic departure from the traditional approach to integration that has emerged as best practice over the past 10-20 years – using templates, checklists, and strong process

management to avoid risk. Even now, this approach produces **M&A failure rates of 66-75 percent.** (McKinsey & Company - Deutsch, and West, 2010)

To summarize it, many researches and studies indicate the failure rate of M&A transactions ranging between 60 and 80% which is an extremely high rate. Having said that, there are different ways of measuring success of M&A transactions and their overall performance.

## **2.2 Methods of measuring M&A performance**

One of the most common methods used in practice to measure an M&A performance and related success is looking at a shareholder return/total shareholder return (TSR)/total returns to shareholders (TRS). In this case, the shareholders of the bidding/buying company tend to underperform from a short term as well as long term perspective, meaning, they do not receive their required return. On the contrary, if you are the shareholder of target company, in majority cases, you benefit from receiving a premium over the current market price of the company's shares you own.

The other methods, also used by the M&A Research Center at Cass Business School in London, comprise looking at the growth in revenues or turnover, an increase or a decrease in margins after the transaction completion, the state of balance sheet, usually used to identify any movements in the leverage of merging company, and analyzing what has been done to the brands and sales, whether the company has been able to retain the business, which means how quickly companies do a sell-off with what they've already bought. In addition, from an underwriting point of view, Schiavone also looks at the impact of particular acquisition on the culture of merging companies and tries to identify how a particular deal would work based on a cultural aspect of merging companies. (Moeller, Schiavone, and Max, 2009)

One of the largest researches on measuring profitability of M&A transactions which have been performed so far, is the research carried out by Robert F. Bruner (2002, 2004), a distinguished professor of Business Administration and Executive Director of Batten Institute at the University of Virginia. His research is based on a summarization and consolidation of the results of 14 informal surveys and 100 scientific studies carried out during the period of 1979- 2001. The final results of his work confirm, but also disprove opinions of many executives, consultants and journalists who assert that majority of M&A destroy company's value. The research comprises the following approaches of measuring profitability of M&A:

- 1) **Event studies** – market based studies which measure abnormal shareholder returns in the period surrounding the public announcement of transaction. The abnormal return is calculated as a raw return less a benchmark of what investors required that day. The raw return for one day is the change in share price and any dividends paid, divided by the closing share price the day before. The benchmark is often represented by the capital asset pricing model (CAPM) or return on a large market index, such as the FTSE100, S&P500 etc..
- 2) **Accounting studies** which are based on assessing financial results of companies (acquirers) before and after the M&A transaction. The main source of information includes company's financial statements, management discussions and analyses reports (MD&As), and proxy statements.
- 3) **On-site surveys/Executive surveys** which comprise putting questions to executives in order to identify whether a purchase of particular entity has created value for their company. Of note, executive surveys may have the form of on-line or paper questionnaires which are directly sent out to executives.
- 4) **Clinical studies** stand for an inductive research which results from a deep analysis of one or many M&A transactions that are based on a detailed screening of facts and company's highly valuable internal information. The information is obtained from on-

site visits of the company, performing field and other knowledgeable interviews with executives and key employees of the firm.

The key outcomes of Bruner's (2002, 2004) research and overall measuring M&A profitability are summarized as follows:

- **Acquisitions are beneficial** to shareholders of target companies, the companies that are purchased. Furthermore, the studies clarify that in case of mergers, the transactions create common synergy value (joint value) for the combined company. Lastly, two third of studies indicate that for bidders alone, the value is conserved (unchanged) or created
- **Acquisitions are not beneficial** from the perspective of acquirer (buyer/bidder) and creating material and significant abnormal value. Under these conditions, this line of reasoning shows that 60-70 percent of all M&A transactions fail. However, from the economics point of view, investors should be pleased if they reach at least the returns which are just equal to their cost of the lost opportunity, defined as their required return. Therefore, the definition of failure is too extreme in this case, since the reality confirms that 60 up to 70% of all M&A transactions is associated with financial results and performance that compensate investors for their opportunity cost. Taking into account the aforementioned fact, the acquirers get at least what they deserve. (Bruner, 2002, 2004)

Despite the research outcomes, there are many other factors which can have a significant influence on the findings above. Therefore, it is difficult and it would not be correct to generalize the hypothesis, whether mergers and acquisitions create value or not, whether they are profitable or they are not beneficial at all.

M&A profitability and success is also markedly dependable on other factors, one of which is a company's strategy of diversification or centralization/focus that company's key executives decide for and apply internally, as well as the way of realization of overall M&A integration and post-integration process. In general, following the results of Bruner's (2002, 2004) research, in terms of return on capital, acquisitions of companies with a similar business strategy and product portfolio focus pay more and are more profitable (with higher returns) and successful for a buying company than acquisitions of companies with a different business and product portfolio focus and strategy.

Another finding of studies reports that investments in the firms of which core business does not relate to and is not part of the core business and strategy of buying company and has a completely different focus, are in most cases unsuccessful. After some period of time, these purchased companies, business units and/or subsidiaries become subjects to partial divestment or complete sell-off.

In addition, the studies reveal that strategic partnerships and joint ventures (JV) are more profitable and successful, if the agreement of mutual cooperation is formed between two companies with a similar core businesses and strategies.

### **3 M&A FAILURES AND WHAT TO DO TO SUCCEED**

The high rate of unsuccessful M&As is affected by many factors which have their origin in mistakes made before, during or after the realization of deal process. Therefore, top managers and executives should learn about common mistakes in order to be able to avoid them during a transaction and post-transaction process, and make right decisions and take the steps which would bring required benefits and guarantee success of entire M&A process.

### **3.1 Common mistakes and reasons behind M&A failures**

Top 10 most common errors which are made by individual participants in an M&A deal process are presented below (Snow, 2011):

**1) Wrong assumptions that the deal is done after the Letter of Intent (LOI) has been signed**

LOI is a document which contains basic information about the planned deal and essentially becomes the foundation of purchase agreement. Both parties, the seller and buyer should note and remember that LOI is not a final agreement on the deal closing, but it opens a door to the next necessary activities in the M&A process such as due diligence and contract writing.

**2) Being unprepared for Due Diligence**

This is very often the most common mistake. Basically, sellers are not ready to provide documents and materials requested by potential buyers in order to ensure a smooth due diligence process. The root of problem is usually in different expectations and thinking of buyer and seller. The buyer expects to get access to the due diligence materials the moment the LOI is signed, however, the seller thinks the deal is done after the LOI is signed. Therefore, in order to ensure a successful process, the seller should start compiling the due diligence materials in the same time he comes up with the offer to sell his company and start marketing it. This way, the buyer gets the access to the requested documents right after the LOI is signed.

**3) High Valuation with no rationale**

This is a mistake that many first-time deal-makers with no previous experience with a purchase or sale of company often make. In majority cases, sellers overvalue their companies based on their feelings and relations they have towards these companies. Their valuations have usually irrationale nature without any professional foundation. In order to avoid further problems and misunderstandings stemming from different opinions on the value of offered company, sellers should not come to buyers without any expert opinion (valuation) on the value of their company, performed by a qualified external or internal appraiser.

**4) Wrong assumptions that buyers won't discover problems in financials**

In the majority of cases, buyers hire specialized advisory and auditing companies to perform financial due diligence and analyses on potential target companies. There is a high probability that these specialists will identify any potential discrepancies or problems in the financials of these targets, if they exist. For that reason, the seller should share with the buyer all the information about problems the offered company has, which enables him to control the situation and frame the argument.

**5) Underestimating the other side's sophistication**

In practice, this mistake appears quite often with buying companies and especially, with buyers from large cities. Underestimating the sophistication of other side causes only problems. In this case, the best practice is to act reversely, which means, to be very careful and prudent with individuals that appear uneducated or unskilled at first glance, because the opposite is most probably true.

**6) Failing to understand who really has the power**

During an M&A process, power oscillates between a buyer and seller. A big mistake made by novice deal-makers is to miscalculate their power. Misplaying a strong hand is bad, but misplaying a weak hand is even worse., because if one side is in a weak position without any other options, it will have to accept the deal being offered. In such case, this side is not in a position to dictate terms.

**7) Withholding material information**

Material information is any information on lawsuits, environmental problems, a loss of important customer, and other important information which has a significant influence on the organization and its operations. An unwillingness to disclose such information indicates that the seller is acting in bad faith and is trying to mislead the buyer through the omission of important data. The seller is obligated to inform the buyer of all material events.

**8) Providing confidential information before the deal is closed**

Depending on the terms and conditions set by the LOI, providing confidential information about the deal to external individuals or any outsiders who are not a part of the deal group or deal team, can be considered as a breach of confidentiality and may represent an illegal action. Special caution needs to be applied in case of publicly traded companies. If an individual or group uses the information to trade (buy/sell) shares on stock market, this action would be considered as committing a crime of insider trading.

**9) Contacting seller's employees without permission**

In practice, there are cases, when the buyer starts contacting employees of selling company and try to inform them about new management, organizational structure or any other sensitive information, before the deal actually closes. Similarly as in previous case, this conduct is unacceptable and may cause untold devastation in the seller's business and entire M&A deal, much like breaking confidentiality can. Therefore, the buyer should only contact and speak with people who know about the deal and to whom the seller agrees to contact.

**10) Contacting seller's customers or suppliers without authorization**

Customers are one of the most important parts of business relationship for any seller. If the buyer contacts seller's customers and informs them about the pending M&A deal, there is a real threat that the contacted customers decides to find a new vendor. This kind of breach can harm the seller and destroy the deal itself. In many cases, it is caused by too hyperactive buyers trying to conduct a deal related due diligence process. In order to avoid any problems, a buyer should always ask for an authorization from a seller to contact seller's customers or vendors.

Following the most common errors, there are many other reasons and explanations why certain M&A deals go well and succeed and others fail. According to Max (Moeller, Max, and Schiavone, 2009), the following reasons stand behind vast majority of M&A failures:

- **Unrealistic expectations of current deal environment** that can give a rise of issues in negotiation process (i.e. negotiations of share price)
- **Buyers don't commit regularly enough due diligence into the early stages** in order to secure an early exclusivity, which gives the right to terminal issues at the latest stages
- **A difference between opinions of the buyer and seller with regards to some contractual points**, mostly warranties and indemnities, particularly pertain to the moment, given the fact that the seller often wants uncommitted capital as a result of the sale

Moeller and Schiavone add that **a post-merger integration (PMI) and its planning** are key factors that very often determine whether a particular M&A deal will be successful.

*„Deals don't fail because of the price, deals don't fail necessarily because of the strategy was wrong and the wrong company was bought. The deal fails after the deal closes.“ (Moeller, Max, and Schiavone, 2009)*

It happens quite often that two merging companies get to the deal closing, think about it as the end, but forget that they haven't put up enough planning into a post-merger integration period, which should include strategies on linking together two different cultures, determining who is going to manage what business, what products are going to be retained and what operations are going to be discontinued. In many cases, a time period after a deal closing is often referred to the time period in which both parties, the buyer and seller, or in case of a merger, two merging companies, can become witnesses to and participants in such things as lawsuit which does tend to happen after closing the deal.

There are plenty of companies which use inside (internal) and/or outside (external) advisors for early stages of M&A process, however, only few of them also do it for an integration process. Most of the time, companies do not even plan who is going to do the integration process or they often refer to a first 100 hundred day plan they might have in place for the period after the closing, but the issue is that an average integration takes more than a hundred days.

Cambell and Smith reveal 5 tips which should bring success and profitability to investors/acquirers/buyers in any of their acquisition processes. (Cambell and Smith, 2012) These advices are aimed to help deal-makers with the execution of their acquisition deals and can be summarized as follows:

- **Tip 1: Every deal needs to generate an incremental value**  
Every deal needs to generate some extra dollars/pounds/euros, simply, extra value from a combination of two organizations. A minimum of 50% - 100% of extra should be required as a result of the combination and related synergy. Most companies often forget that the whole purpose of doing a deal is to create an incremental value.
- **Tip 2: Listen to your advisers very selectively**  
The reason behind is that the vast majority of acquiring companies negotiate a fee with their advisers which is contingent on the deal going ahead. Most of the time, they get advisers who are motivated to do the deal, even the things begin to look bad. Consequently, the companies have to be aware that advisers are going to incline them to do the deal even if they feel it is maybe not the right thing to do. So, they have to be very carefully and listen up what advisers say.  
Cambell and Smith mentioned (2012) that in this case, Buffet's recommends that very large acquisitions should have a consultant who only gets paid (only get a bonus), if the deal doesn't go through. So, in the deal team, where there are many advisers working to put the deal through and get paid when the deal happens, there should also be at least one person who is only paid if it doesn't happen. (Cambell and Smith, 2012)
- **Tip 3: Look for the deals which are primarily driven by revenue synergies**  
The deals with extra sales from cross selling, extra sales from having a stronger position in a particular market place, extra sales from better utilization of technology or other revenue synergies, perform better than the deals that are driven primarily by cost savings.
- **Tip 4: Create an implementation plan and plan it early**  
A buyer should make an implementation plan long time in advance in order to make sure he knows who is going to be involved in delivery of the implementation process of his acquisition. On top of that, the buyer should make sure that those people are also involved in the acquisition itself. What he should try to build here is a commitment and the commitment comes when he buys in into the process. The buyer should want the same people to participate in creating the acquisition plan as well as

being responsible for delivering it on the deal later. Buying in and then being responsible for delivery is critical. Therefore, it is very important to create an implementation plan early and make sure to get delivery on it.

▪ **Tip 5: If you fail, then fail safe**

Cambell and Smith (2012) mentioned a Buffet's advice, which says that acquirers should build in a margin for errors, meaning that even if the things don't turn out as the paper work suggested, as it was initially planned, the deal still looks good. This is true for acquisitions just as it is for investing in stocks and shares. The advices for deal-makers are as follows:

- if you find yourself "scraping the barrel" to generate enough synergies, to justify the deal price, do not do it, go back
- if you find you haven't got the management that you would ideally like to have to lead the implementation process, cut off negotiations
- if you are not convinced that the other side is being completely straight forward with you and the deal is tight one, don't do the deal unless you are comfortable that the deal you are doing is going to create lots of value and has a room for it to be worse than you thought it is going to be. Otherwise you are chasing a wrong sort of deals. Most deals look much worse 3 years after than the day negotiations were closed. (Cambell and Smith, 2012)

There are many factors which stem from internal enterprise processes and its efficiency rather than external ones, that directly influence enterprise value of particular company. This is also applicable for any M&A transaction activity. If a management team of company decides to carry out the expansion of company's business through M&A activities, it does not automatically mean that by increasing the value of company's assets as a result of purchasing a target company or merging with other company, the total intrinsic value of newly created legal entity will increase as well. The reason behind is quite simple. In many cases, a synergy effect of two merging organizations is highly dependable on the overall transaction and post-transaction processes executed within these organizations. For many investment banks and consulting firms, the success of M&A transaction ends with signing a deal and cashing out benefits in the form of advisory fees, However, for merging organizations, this is just a beginning of long way towards success which can also turn out as a big failure. In general, a positive impact of particular M&A transaction and its prosperity can be identified in the first months or years right after the transaction realization and performing deep analyses and scrutiny.

## **4 CONCLUSION**

The turbulent time full of changes, accompanied by the recession which the world economy currently cope with, is not easily manageable from a management point of view since it is difficult to retain a historical sustainable growth or at least to achieve the results from before the year 2008. Nowadays, many executives have to deal with the decision making process whether to accept or deny restructuring means, one of which is M&A. There is no guidance or instruction book to achieve a 100% success of M&A transaction, however, there are general principles which if they are applied correctly, there is a high probability that the results, required by investors, managers and/or other stakeholders of company, will be reached.

## **ASSESSMENT AND EVALUATION OF THE IMPACT OF FINANCIAL RISK ON SMALL AND MEDIUM-SIZED ENTERPRISES IN SLOVAKIA**

*Mária Hudáková, Katarína Buganová, Ján Dvorský*

### **Abstract**

The enterprise exists in the area, which is subject to permanent changes, and most of these changes are caused and evoked by the very man. The way how to deal with these changes also depends on the ability of the enterprise to adapt and accept the variability of daily life. In the interest of each enterprise, whether it is small or medium-sized, introduction of risk management and assessment of current financial situation should be in relation to the potential risks. Small and medium-sized enterprises (SMEs) in Slovakia do not pay sufficient attention to financial risks; do not make assumptions or preventive measures of the risks assessed that would prevent financial problems or financial crisis in the enterprise. The essence of the article is, based on the collected and processed data from the statistical survey, to assess and evaluate the impact of the financial risk on small and medium-sized enterprises in relation to the length of the business and the number of employees in the Žilina region of Slovakia.

*Keywords: risk, finance, management, analysis, small and medium-sized enterprise*

JEL Classification: M21, G32, L52

## **1 INTRODUCTION**

The economic performance of small and medium-sized enterprises has a major share in production capacity and employment, and how Beck, Demircus and Levine (2005) illustrate, the presence of a prosperous SME sector is one of the characteristic features of the developed economies. Small and medium-sized business is no longer perceived as a social good to be maintained despite its economic costs, but on the contrary, a significant contribution to economic development (Mukwasi, Seymour, 2012). Today, small and medium-sized enterprises are increasingly perceived as the primary tools for the development of entrepreneurship and do not contribute to the creation of job positions and socio-political stability, but to the innovation and the competitiveness of the national economy as well (Belás, et al, 2014).

The Slovak corporate economy is greatly dependent on small and medium-sized enterprises, because they create 72% of job positions and 67% of added value what extends respective averages of the EU (67% and 58%). The majority of enterprises operate in the field of services and retail trade, but the production also represents an important sector. Although it does not include a very high number of SMEs, it constitutes 25% of job positions and 22% of added value creating SMEs within the corporate economy (SBA Survey, 2014).

In particular, regional disparities represent an important issue in the framework of the Slovak Republic. Lessman (2009) noted that Slovakia had the highest level of regional disparities among the OECD countries in the five-year average for the period 1996 – 2000. On the contrary, as Habánik, Hošťák, and Kútík (2013) demonstrated that the rate of regional disparities from 2002 to 2010 deepened even more. Although economic performance of the whole country converges towards the level of the European standard, the economic growth,

however, is concentrated in Bratislava region and the economic performance, mostly of rural regions, still lags behind. In this context, there arises extremely important need to examine the economic phenomena in the Slovak Republic, not only at national but regional level as well.

**The aim of article** is, on the basis of the data obtained and processed from the statistical survey, to assess and evaluate the impact of financial risk on small and medium-sized enterprises in relation to the length of the business and the number of employees in the Žilina region of Slovakia. The length of the business and the number of employees in the enterprise are important factors, which may or may not affect the size of the financial risks and their management. The results obtained from the survey are based on the experience of business owners of SMEs, managers, and their attitude towards risk as well as their ability to manage risk.

In order to meet the stated objective, there were used **empirical methods of research** (questionnaire, interview with competent SME persons), **statistical methods** i.e. analysis of variance using quantitative tools of statistics (percentage, average values, homoscedasticity, Cochran's test, Bartlett's test, Levene's test, Kolmogorov-Smirnov test, F-test, Kruskal-Wallis test, Box-and-Whisker plot, graph of mean values) and **statistical software** Statgraphic centurion XV (Software Statgraphics Centurion XV, 2014).

## **2 IMPORTANCE OF FINANCIAL RISKS IN SMALL AND MEDIUM-SIZED ENTERPRISE**

In foreign sources is **financial risk** (Guzman, 2015) refers to the chance a business's cash flows are not enough to pay creditors and fulfil other financial responsibilities. The level of financial risk, therefore, relates less to the business's operations themselves and more to the amount of debt a business incurs to finance those operations. The more debt a business owes, the more likely it is to default on its financial obligations. Taking on higher levels of debt or financial liability therefore increases a business's level of financial risk. Holton (2004) argues that there are two ingredients that are needed for risk to exist. The first is uncertainty about the potential outcomes from an experiment and the other is that the outcomes have to matter in terms of providing utility. Risk factors play three distinct roles in financial analysis (Brammerts, et al., 2009):

1. Risk factors are drivers for the calculation of expected cash flow, for example interest rates directly influence the magnitude of interest payment cash flows, FX rates determine the value of cash payments in base currency, credit risk effects reduce expected cash flows and insurance risk causes future cash flows to be paid out.
2. Risk factors – especially interest and FX rates – determine the values within the lifetime of the contracts via discounting functions.
3. Risk factors are random variables introducing variance into the financial system.

In the opinion of Brammerts (2009) are the following main financial risks categories:

- market risk,
- credit risk,
- insurance risk,
- operational risk.

**Financial risk** belongs among economic (operational) risks with the defined impacts on enterprise finance. According to Markovič (Vlachynský, Markovič, 2001), financial risk represents the probability of the occurrence of financial loss or gap of profit as a result of operational development compared to the development expected. Financial risk is mostly

caused by movements in the financial markets and changes of subject attitudes towards individual financial tools and individual transactions (Zanická Hollá, et al., 2010). The impact on enterprise results is imminent, just as there is a bearer or source of risk in the portfolio of the enterprise. When defining the financial risk of the enterprise, Jilek (2000) talks, among others, about the losses, which may result from the financial or commodity tool, or financial portfolio. In summary, financial risks are associated with the availability of sources of funding, insolvency, indebtedness of an enterprise, adverse changes in interest rates, exchange rates, etc. They are very important for the analysis of the business plan and strategic decision making (Hudáková, et al., 2014).

According to Markovič (2007), financial risk is divided into:

- Credit (direct credit risk, credit equivalent exposure, settlement risk, large credit risk exposure)
- Liquidity risk and liquidity
- Price risk (interest rate risk, equity risk, currency risk, commodity risk)
- Operational and legal risk

There are current data in Slovakia showing that credit conditions improved in 2013 (Statistical office of the Slovak Republic, 2013), while only a small number of Slovak entrepreneurs informs about the reduced willingness of banks to provide credit and lower availability of public financial support including guarantees (Belás, 2013). The share of enterprises established (i.e. companies doing business and paying the wages of more than three and half years) is lower, suggesting a lower survival rate.

However, business plans slightly above average, whereas 16% of Slovaks wanted to establish a new business in the near future. According to "SBA Survey 2014", there is a below-average support for honest entrepreneurs in Slovakia who were not successful and want to start a business again (SBA Survey 2014). The time necessary to resolve insolvency was double in the Slovak Republic in 2014 compared to the EU.

According to a survey on business risks focused mainly on young entrepreneurs; authors – Jakubec, Sobeková Majková and Solík (2012), it was found that young entrepreneurs often face the lack of start-up capital within the financial risk. Only a third of young entrepreneurs indicated that they had sufficient capital when setting up a business. The survey revealed that young entrepreneurs growing up in the business family are more likely to have sufficient start-up capital (42%) than other population (23%). Since the outbreak of financial and economic crisis, secondary insolvency has represented a major problem chasing entrepreneurs and threatening their existence. In particular, it can cause annoying problems for young entrepreneurs who have not created sufficient financial reserves. Up to 44% of respondents participating in the survey had problems with secondary insolvency. Their problems with non-payers were severe enough to endanger their ability to pay suppliers (Májková-Sobeková, 2011).

A large international study, carried out by The Economist Intelligence Unit and Dun & Bradstreet (Customer and Supplier Risk Management, 2013) demonstrated that enterprises, not only manage the risk, but also regularly evaluate the success of its management, perform better results. Enterprises are dependent on reactive fire-fighting problems arising without a systematic approach. Financial risk management (such as currency and interest rate risk) and the risks associated with insolvency of customers are considered a matter of course abroad.

According to an international survey Treasury Risk Survey focused on global trends in enterprise risk management in 2013, which was carried out by the Association for Financial Professionals (CFO, 2013), in cooperation with Zanders Treasury and Finance Solutions,

European companies consider liquidity, currency and reputation risk to be the most serious threat for their business.

### 3 RESEARCH METHODOLOGY AND RESULTS

There was made the statistical survey of business risks for small and medium-sized enterprises in the Žilina region, within the framework of the project FaME/2013/MSPRISK: "Current trends in the area of business risks of small and medium enterprises in selected regions of the Czech Republic and Slovakia". There were 164 small and medium-sized enterprises polled in the Žilina region using the form of empirical examination (questionnaires and interviews with the competent persons of SME). The structure of enterprises was as follows: 17% was involved in production, 21% in commercial activities, 17% in construction enterprises, 6% in transport enterprises, 1% in agricultural enterprises, and the largest share was formed by enterprises, which provided business in other sectors 38% (consulting, distribution, etc.). 58.54% of the entrepreneurs in the Žilina region stated financial as the second key business risks at the moment. There are business risks analysed in Figure 1:

- blue column shows **importance or key significance of business risk** for SMEs (calculated as the ratio of the number of respondents who reported a given answer to the total number of companies),
- red column shows **average value of SME's risks identified** (calculated as arithmetic mean of values reported by entrepreneurs in the Žilina region).

Fig. 1 – Percentage of the importance and average value of the SMEs risks identified in Žilina region Source: elaborated by authors

The survey shows that 67.68% of enterprises can largely manage financial risks, 23.17% claim they can properly manage financial risks. Only 1.83% thinks they do not know how to manage financial risks. It is admittedly a subjective assessment of their own abilities of entrepreneurs; however, we can say that this ability may be partially supported by a fairly decent educational structure of entrepreneurs.

According to the objective established at the beginning of the article, and with the use of statistical methods and tools, we examined whether the factors such as the length of business and the number of employees in the enterprise in the Žilina region caused impact on the average (mean) values of the intensities of financial risks. In order to meet the objective, there was used a quantitative method - "analysis of variance". Analysis of variance was determined by either a parametric or non-parametric test (Betáková, et al., 2010). There should be met two essential conditions for the calculation of parametric test that the resulting p-value of the financial risk of homoscedasticity test (i.e. identity of variance) and test to verify the normality of SME groups must be higher than the level of significance of 0.05.

It was divided into three groups, according to the length of the business and the number of employees in the enterprise (Table 1).

Tab. 1 – Distribution of SMEs according to the length of business and number of employees.

	<i>SMEs</i>	<i>Financial risk</i>
SME groups according to the length of business	SMEs from 1 to 5 years	24
	SMEs from 5 to 10 years	34
	SMEs more than 10 years	39
SME groups according to the number of employees	Micro-enterprise (up to 9 employees)	66
	Small enterprise (10 – 50 employees)	16
	Medium enterprise (up to 499 employees)	15

Basic statistical characteristics (BSC) necessary for the analysis of variance are listed in Tab. 2:

- $\mu$  – average value of the risk to the enterprise,
- $\sigma$  – standard deviation of the risk value to the enterprise,
- $\sigma^2$  – variance of risk values to the enterprise.

Tab. 2 – Basic statistical characteristics (BSC) of the financial risk in the three groups of SMEs according to the length of the business and the number of employees. Source: elaborated by authors

	<i>SMEs</i>	<i>BSC</i>		
		$\mu$	$\sigma$	$\sigma^2$
SME groups according to the length of business	SMEs from 1 to 5 years	31.67	15.44	238.39
	SMEs from 5 to 10 years	32.79	12.92	166.92
	SMEs more than 10 years	33.77	14.02	196.56
SME groups according to the number of employees	Micro-enterprise (up to 10 employees)	31.74	13.48	181.92
	Small enterprise (up to 50 employees)	40.33	13.95	194.52
	Medium enterprise (up to 250 employees)	34.36	14.74	217.45

### 3.1 Comparison and assessment of the basic statistical characteristics of financial risk for SMEs according to the length of business

It was not possible to use the parametric test of mean risk values for the analysis of variance of financial risk. As the conditions were met, there was carried out non-parametric test of the financial risk medians in three groups of SMEs according to the length of business in the Žilina region. We have verified the condition of homoscedasticity – identity of variance of different groups using the following tests:

- Cochran's test: p-value = 0.537,
- Bartlett's test: p-value = 0.650,
- Levene's test: p-value = 0.980.

It is possible to conclude out of the results of the individual tests that the resulting p-value was greater in all the tests as the level of significance we had chosen. The condition of a normal distribution of financial risk evaluation in enterprises, according to the business times using the Kolmogorov-Smirnov test:

- p-value of enterprises with a business period from 1 to 5 years is 0.032,
- p-value of enterprises with a business period from 5 to 10 years is 0.487,
- p-value of enterprise with a business period over 10 years is 0.101.

We refuse the assumption on the surface of significance that the evaluation of the enterprises with the business period from 1 to 5 years originated from the normal distribution.

Tab. 3 – Analysis of variance of the intensity of financial risk according to the length of business. Source: elaborated by authors

	<i>Number of enterprises</i>	<i>The average in group</i>
Enterprise from 1 – 5 years	24	44.2083
Enterprise from 5 – 10 years	34	49.4559
Enterprise more than 10 years	39	51.5513

*P-value = 0,590*

In consideration of the fact that the calculated p-value of Kruskal-Wallis non-parametric test of the analysis of variance is greater than 0.05, we can say that there are no statistically significant differences among medians of intensity rate of the financial risk according to the length of the business of small and medium-sized enterprises in the Žilina region with reliability 95.0%.

Fig. 2 – Multiple Box-and-Whisker plot of financial risk according to the length of business. Source: elaborated by authors

Graphical analysis of financial risk confirmed the results of testing using analysis of variance. We can say that the length of business did not affect the assessment of the financial risk of SMEs in the Žilina region.

### 3.2 Comparison and assessment of the basic statistical characteristics of financial risk for SMEs according to number of employees

It was not possible to use parametric test of mean risk values for the analysis of variance of financial risk. As the conditions were met, there was carried out non-parametric test of the financial risk medians in three groups of SMEs according to the length of business in the Žilina region. We have verified the condition of homoscedasticity – identity of variance of different groups using the following tests:

- Cochran’s test: p-value = 0.934,
- Bartlett’s test: p-value = 0.928,
- Levene’s test: p-value = 0.958.

It is possible to conclude out of the results of the individual tests that the resulting p-value was greater in all the tests as the level of significance we had chosen. The condition of a normal distribution of financial risk evaluation in enterprises according to the number of employees using the Kolmogorov-Smirnov test:

- p-value of enterprises with the number of employees up to 10 is 0.003,
- p-value of enterprises with the number of employees up to 50 is 0.701,
- p-value of enterprises with the number of employees up to 250 is 0.433.

We refuse the assumption on the surface of significance that the evaluation of micro-enterprises with the number of employees up to 10 originated from the normal distribution.

In consideration of the fact that the calculated p-value of Kruskal-Wallis non-parametric test of the analysis of variance is smaller than 0.05, we can say that there are statistically significant differences among medians of intensity rate of the financial risk according to the number of employees of small and medium-sized enterprises in the Žilina region with reliability 95.0%. Table 4 shows that the median of the assessment of medium-sized enterprises in respect of financial risks is on average about one-third higher than in the assessment of micro and small enterprises in the Žilina region in Slovakia.

Tab. 4 – Analysis of variance of the intensity of financial risk according to the number of employees. Source: elaborated by authors

	<i>Number of enterprises</i>	<i>The average in group</i>
Micro-enterprise	66	42.77
Small enterprise	16	61.57
Medium-sized enterprise	15	48.36

P- value = 0,042

Fig.3 – Multiple Box-and-Whisker plot of financial risk according to the number of employees. Source: elaborated by authors

Graphical analysis of financial risk confirmed the results of testing using analysis of variance. We can say that the number of employees affected the assessment of the financial risk of SMEs in the Žilina region.

#### **4 ASSESSMENT OF RESULTS**

The results of the statistical survey carried out in Žilina region are based on the limited sample of respondents for SMEs in the Slovak Republic. On the basis of the results of the survey, using basic statistical characteristics and financial risk analysis of SMEs, we can conclude that the financial risk does not depend on the length of business activity in the Žilina region. In spite of the fact that the results of the survey indicate the independence of the factors assessed, financial risk may arise from various aspects of business during the whole enterprise activity. One of the most common causes of enterprise termination is incorrect calculation of start-up capital and very often underestimated calculations of unit costs, incorrectly calculated prices of goods and services, errors in accounting (taxes, levy), high initial investments and insufficiently or improperly secured funding resources (own, foreign).

From the point of view of the financial burden, the largest source of risk is high charge burden with the negative effect on the amount of the total value of the work and is challenging. As confirmed by the results of the survey. Using basic statistical characteristics and analysis of financial risk of SME, we can conclude that financial risk is dependent on the number of employees in the Žilina region. It follows that the financial risks in the form of operational risks, which are usually caused by human error or technical failure, may lead to financial losses. These are the risks that are mostly short-term in duration, but the possible negative effects of the crisis situations arising as a result may have broad and disastrous consequences (threat to property, health, life).

SMEs can manage risk in several ways. One of the options, which, however, a lot of SMEs does not use, is to create financial reserve of enterprise for a period of recession. This is due to limited financial resources. Therefore, in the field of SMEs, it is recommended to move risk to business partners. In terms of functioning of financial markets and insurance market, which provides a number of products and credit, one of the best ways how to reduce the risk is to secure or insure it. A higher level of planning requires reducing the risk by diversifying into different commercial activities. Diversification of risks into the various activities requires the combination of financial resources. Securing funding through loan products or other available resources to support SMEs requires processing of a detailed financial and cash-flow plan, taking into account the potential risks of the business.

#### **5 CONCLUSION**

Most enterprises abroad have already integrated risk management into its planning and decision-making process, i.e. they systematically consider possible risks when taking decisions in the areas such cash flow management, investing, pricing. The implementation of enterprise risk management is seen as the biggest potential for how to make risk management effective. In Particular, medium-sized enterprises in Slovakia should have integrated risk management in an effort to improve prevention of risks, i.e. to centralise risk management into a single department and create teams composed of various departments to manage different types of risks.

The biggest barriers that prevent enterprises in Slovakia to effectively manage financial risks relate to problems with the availability of information, whether internal or external data necessary to evaluation and management of risks, or integration into the decision-making process. Financial risks are identified only from the data in the accounts and internal rate of profitability, after their implementation (establishment). On the basis of existing experience, many managers are based on the knowledge of past. However, to evaluate the risk only on the basis of own experience and feelings is currently inadequate. The factors such as the length of business and number of employees surveyed revealed that their impact on the level of financial risk is not possible to ever underestimate. Therefore, the owners of SME in Slovakia and responsible managers must rethink their approach to the evaluation and management of financial risk and consider the rate of financial resources and implement steps to manage financial involved.

## **CREATING MOBILITY OF RESIDENTS ON AN EXAMPLE OF MEDIUM-SIZED CITIES IN POLAND**

*Katarzyna Cheba, Maja Kiba-Janiak, Sebastian Saniuk, Krzysztof Witkowski*

### **Abstract**

The paper presents the application of selected methods of multivariate statistical analysis including factor and conjoint analyses in terms of modelling transportation preferences of urban residents. The introduced methodologies can be useful tools for local authorities while designing solutions in order to improve the competitiveness of public transport as an alternative to private transport. The results of the studies presented in the article are part of the research project implemented in 2010-2013 under the title "Reference model of city logistics and the quality of life". For the study undertaken in this paper, three medium-sized cities, located in the western part of Poland, were selected. The structure of the paper is as follows. The second section presents the determinants of change in communication behavior of urban residents, while the third section includes the significance of the applications of multidimensional statistical analysis in order to identify citizens' transportation preferences and behaviours. The subsequent section introduces the research results and the final part of the paper presents the conclusion.

*Keywords: transportation preferences, factor analysis, conjoint analysis.*

JEL Classification: R41, L51, C10.

## **1 INTRODUCTION**

Life in the city and the areas directly adjacent to cities is becoming more and more difficult. The main reason for this situation, besides environmental pollution and security threats, is the constantly increasing number of residents which causes difficulty with movement. The effect of dynamic urban development in urban and industrial agglomerations is often congestive transportation, also called congestion. The problem of congestion is the subject of numerous studies (Tulpule, 1973; Brandeau and Chiu, 1992; Kerner et al., 2000; Cooper et al., 2004; Downs and NetLibrary, 2004; Richardson and Bae, 2008; Badyda and Kraszewski, 2010; Beim, 2012).

The growing wealth of societies and consequently greater access to passenger cars is responsible for the significant increase of the motorization index with a simultaneous fall in public transportation usage (Downs and NetLibrary, 2004; Welzl, 2005, Płachciak, 2009). Forecasts of the European Commission indicate that passenger individual transportation will have increased by 51% by 2050, while the public transportation will further deteriorate (European Commission, 2012).

The impact of transport on the urban environment depends on many different factors. A special place among them is taken by the implementation of the transportation service, which is an important part of strategy for urban transport. The right choice of development strategy, especially public road transport, can help to solve the problems of traffic organization. It is important in this case the proper identification of existing and future challenges that the transport system faces and the formulation of transport development programs that meet

identified tasks in changing environmental conditions (Kerner et al. 2000; Richardson and Bae, 2008, Jurkonyte, 2009).

Factors which can motivate citizens to use urban public transport or other alternative ecological means of transport can be innovative solutions related to the transport itself as well as to creating communication behavior. The implementation of solutions which enable the improvement of transport organization in the cities requires significant financial outlays. The necessity of this kind of investment is very often the most important factor which limits the interest of local authorities in these solutions.

The purpose of the study is an attempt to model transportation preferences of urban residents in one of the medium-sized cities in Poland. In this paper the selected methods of multivariate statistical analysis including factor and conjoint analyses were proposed. The study results can be a useful tool for local authorities in order to design solutions that improve the competitiveness of public transport to private transport. The results of the studies presented in the article are part of a project implemented in 2010-2013 titled "Reference model of urban logistics and the quality of life". The structure of the paper is as follows. The second section presents the determinants of change in communication behavior of urban residents, while the third section included significance of the application of multidimensional statistical analysis in order to identify citizens' transportation preferences and behaviors. The subsequent section introduces research results and the final part of the paper presents the conclusion.

## **2 DETERMINANTS OF CHANGE IN COMMUNICATION BEHAVIOR OF URBAN RESIDENTS**

The communication behavior of urban residents of the European Union has experienced very intensive changes in the last two decades. These changes are essentially similar in nature; however a difference is seen in their pace and the identified phase of the progressive process. In many cities of Western Europe, especially in Scandinavia, Germany and Austria since more less the mid of the first decade of the 21st century there a much slower growth rate of automotive use has been observed, and even a fall has been seen. These trends are consistent with the forecasts formulated several years ago concerning the development of automotives, which implied saturation of individual vehicles. The forecasts developed by the UK government forecast centre in the 1970's assumed the occurrence of such saturation in about 2010 and, in fact, in most cases they correspond to the current situation in the major cities of the European Union (Banister and Berechman, 2003).

These trends occur differently in the cities of Central and Eastern Europe, where a sharp increase in individual automotives is being observed accompanied by a decreasing interest in other means of transport (Cheba and Kiba-Janiak, 2013). Identified related changes are the result of many factors, among which an increasingly important role is attributed to cultural and social changes. Factors that may stimulate the return of the public interest in public transport or other alternative forms of getting around the city by its inhabitants may be innovative solutions for both the transport and development of communication behavior. The rate and nature of changes in transport behavior of urban residents in both Western Europe and in Central and Eastern Europe is conditioned by many diverse factors. The findings of the communication behavior of people in most European cities indicate that primarily cultural and social factors play a major role and only later economic and environmental ones. It should be noted, however, that the intensity of the observed changes and the dominant nature of these and other factors is directly related to the wealth of society. In Western Europe, the automotive factor in major cities now typically ranges from 350 to 400 cars, whereas 5-10 years ago its level was mostly at the level of more than 400 cars per 1000 inhabitants.

Observed in the statistics of these countries that increase relates primarily to the automotive industry areas outside the cities (Cooper and al., 2004; Badyda and Kraszewski, 2010; Beim, 2012).

The situation is very different in most cities in Poland (a similar situation also applies to the Czech Republic and Hungary), in which there has been significant growth in the automotive industry. In the ten largest cities in Poland, the level of motorization in 2013 ranged from 447 (Lublin) to 598 (Warsaw) passenger cars per 1,000 inhabitants, while in cities such as Krakow, Katowice, Poznan, Wroclaw, Gdansk this level is much higher than 500 cars per 1000 inhabitants. After 1989, an accelerated process of development of the automotive industry was observed in Poland, similar to that which Western countries experienced many years before. Changes taking place as a result of it are relevant to contemporary cities. Changing social, economic, cultural, and technological conditions is a serious challenge for existing communication systems in cities in which such a rapid growth of the automotive industry was not taken into consideration.

Tab. 1 – The changes of the motorization rate. Source: own elaboration on Eurostat data.

Cities	2007	2008	2009	2011	2011/2007
Bruxelles / Brussel	483,0	485,8	479,1	451,3	-6,56%
Berlin	290,2	286,9	285,7	290,2	0,00%
Frankfurt am Main	321,5	319,6	316,9	319,9	-0,50%
Madrid	482,5	484,6	476,8	467,7	-3,07%
Barcelona	378,3	381,3	376,3	370,1	-2,17%
Paris	250	244,3	238,5	233,4	-6,64%
Sofia	475,3	518,1	570,6	654,9	37,79%
Praha	515,5	513,9	508,5	540,7	4,89%
Warszawa	510,7	555,6	533,4	564,8	10,59%

Fig. 1 – Formation of the motorization rate (the number of passenger cars per 1000 inhabitants) in selected European cities in the years 1990-2012. Source: own elaboration on OECD data.

The most important problem, apart from a rapid increase in the number of cars, is also a significant increase in road freight transport, which puts a burden on municipal systems. Free communication is becoming more and more difficult due to the development of housing in suburban areas or placement of large shopping malls outside the concentrated urban housing (Brandeau and Chiu, 1992; Potts, 2002) areas. Road congestion, especially in big cities, has caused a decline in the quality of public transport travel which is reflected in a reduction of the speed of communication, loss of regularity and punctuality of vehicles; an increase in the degree of uncertainty to reach your destination at the scheduled time (Downs and NetLibraray, 2004; Janecki and al., 2010). All these negative effects of increasing automotives were felt much earlier in Western Europe and became the drive for changes in the common transport policy of the European Union (European Commission, 2012).

The main objective of the most important documents of the EU transport policy, such as: White paper – European transport policy for 2010: time to decide" in 2001, White paper - "Roadmap to a Single European Transport Area - Towards a competitive and resource efficient transport system " in 2011 and Green Paper – “Towards a new culture for urban mobility” in 2007, is, in the case of public transport, to create the conditions for the development of competition by, among others, the liberalization of passenger transport market. To this end, EU documents require the separation of an organizer’s functions from freight carriers’ function.

Measures, that should lead to the economic growth as a result of the growth of innovation and competitiveness of the regions (thanks to regional specialization) are continued in the next strategic for the European Union document entitled Europe 2020 Strategy. This document implies the need for so-called smart specialization of regions. The strategy of smart specialization is defined as a national or regional innovation strategy, whose main goal is to build a competitive advantage due to the development of research and innovation capacity. (Europa 2020).

Sustainable transport is one of the important areas determining the the future development of the economy of the European Union. It should however be noted, that this is an area primarily supporting the development of other sectors of the economy, for which it constitutes a service industry, and its situation is strongly correlated with the condition of the economy as a whole. This information confirms the position of this field among the regional smart specializations in the European Union as the industry supporting the development of other important regions of specialization. In Poland, this sector has been indicated as one of the leading specialization in only five voivodships: kujawsko-pomorskim (Transport, logistics, trade – waterways and land routes), podkarpackim (Aviation and Space Flight), warmińsko-mazurskim (The economics of water including water transport, such as: cruise passenger, water transport of goods, transport of boats and yachts), wielkopolskim (Industrial processes and transport), zachodniopomorskim (Maritime activities and logistics). In other EU countries such specialization has been indicated in regions, such as.: Cyprus (Transportation: Marine, Shipping, Intelligent Transport Systems, road freight), Czech Republic (Transport means (automotive, aerospace, including connected ecosystem of supplying and supporting industries), Berlin (Transport, mobility & logistics), Nord - Pas-de-Calais (Transport and Ecomobility), Lithuania (Transport, logistics and ICT).

### 3 THE STUDY OF TRANSPORTATION PREFERENCES AND BEHAVIOR OF URBAN RESIDENTS

#### 3.1 Modelling assumptions

The modelling of travelers' transportation behavior is a part of a more complex modelling process of travel, which is conditioned, among other factors, by the density of urban networks and associated with the traffic interference or lengthening of the journey time. (Leea and Rivasplata, 2001; Starowicz, 2010, Szoltysek, 2011)

An important element of this process is to study the preferences of buyers, in this case travelers. Knowledge of the preferences and transportation behavior of the inhabitants is essential in the process of shaping transportation offer (Niemczyk, 2014). Particularly important in this regard are studies on: the identification and prioritization of traffic demands and satisfaction with services and comprehensive assessment of the quality of transportation services. It is assumed that the fundamental postulates reported by residents to the urban transport sector are: punctuality, directness, frequency and availability, making up the level of passenger satisfaction with the services provided. An important problem in the course of a lot of research is the correct interpretation of numerous, interlinked information. The solution to the problems with too much individual information can be e.g. a reduction in dimensionality and search for the interplay of many factors, e.g. on the basis of factor analysis.

Factor analysis is used to convert the mutually correlated system of variables into a new system of variables to be determined as common factors mutually uncorrelated, comparable with an output system (Green and Wind, 1975; Green and Srinivasan, 1990; Green, 1997).

The use of factor analysis requires fulfilling the following assumptions (Green and Carmone, 1977; Hair et al., 1995; Walesiak and Bąk, 2000):

- a) linearity and monotonicity of relationships between variables,
- b) normal or close to a normal distribution of variables,
- c) using variables with terms of at least 5-7 answers,
- d) adequate number of observations (above 100, optimally 2000 cases),
- e) the ratio of the number of variables corresponding to the number of observations (the ratio should be 1 to 3 or even 1 to 5).

The construction of the factor model proceeds in several stages. The first step is the construction and initial analysis of the correlation matrix between the original variables. The factor analysis can be applied only if there are sufficiently high correlation coefficients between the variables under consideration. The next step is to choose the appropriate factor model (orthogonal or diagonal), which identifies the method of choosing factors (in the segmentation studies the most commonly used is an orthogonal identification) and a factorial method. These methods can be divided into: methods numbered among principal component analysis (*Principal Components Analysis*) and methods of factor analysis such as a method of main factors.

Prior to testing, one can also try to assess the adequacy of the assumptions of factor analysis. For this purpose KMO statistic was used (*Kaiser-Meyer-Olkin Measure of Sampling Adequacy*). Therefore to confirm the importance of received results Bartlett's test was used. In Bartlett's test there was as a very large discrepancy. The value of chi-square statistics measuring these differences amounted to 2273,51, and the associated risk of confusion (significance), while recognizing the importance of all coefficients is less than 0,001. The

degree of adequacy of tests for the assumptions of factor analysis measured by KMO statistic was 0,898. It is a very good result (the interpretation of the value of KMO by Keiser: 0,9 - wonderful, 0,8- worth praising, 0,7 - good, 0,6 - the average, less than 0,5 - not acceptable). In the next stage of the research in order to determine the optimum number of factors (hidden variables) a method of eigenvalue greater than unity was used as well as the criterion of Cattelan's landslip (*Factor Scree Plot*).

Another method of measuring the preferences of buyers is conjoint analysis (Hair et al., 1995). The essence of conjoint analysis is to evaluate a set of profiles (real or hypothetical products and services) described with the selected attributes (explanatory variables) in order to obtain information about the overall preferences for the profiles (a set of values of the dependent variable) made by the respondents to the survey.

The complexity of the test procedure in the framework of conjoint analysis requires decision-making at every stage of research including among others determining (Walesiak and Bąk, 2000):

- a) the form of the model (depending on model variables, model preferences),
- b) the choice of how to collect data (solid profiles, pairwise comparisons, the presentation of pairs of attributes),
- c) the choice of the presentation profiles (physical product, the product model, a verbal description of figure),
- d) the scale of preferences (nonmetric, metric) estimation method: (nonmetric estimation methods: MONANOVA, PREFMAP, LINMAP, CCM; metric estimation methods: KMNK, MSAE; probabilistic estimation methods: MNW, EM,
- e) assessing the credibility of the model (rating accuracy, reliability assessment),
- f) the interpretation of the results of measurements and the sample size determined mostly on the basis of earlier research (typical test is usually from 300 to 550 respondents).

In the work the analysis of travelers' preferences was based on the research sample, which consisted of adult residents of three Polish cities of West Poland who were between 18 and 70 years of age (Kiba-Janiak and Witkowski, 2014). An attempt was selected from the population at random. The total sample size was set at 1600 inhabitants.

However, the changes may in some cases cause the decline in the quality of services provided which is a direct result of the lack of integration of activities and separation of the areas determining the quality of the services provided which are under the responsibility of the organizer and service provider. Separation of responsibilities in the lack of integration – a service provider will provide the service in the manner and under the conditions specified by the organizer of this service - perhaps in the case of perception of the service offered as a whole, which consists of both elements which the organizer and the carrier are responsible for, in the lack of common policies aimed at increasing the quality of services provided it can impact negatively on this quality.

### **3.2 The results of travelers' transport preference**

The respondents evaluated 12 different quality criteria concerning urban transport services, estimated from the available literature on the subject studies of this type. In the study of exploration the following dimensions of evaluation were considered:

- a) punctuality of vehicles (x1),
- b) frequency of vehicles (x2),
- c) travel safety (x3),

- d) the conditions of travel in vehicles ( $x_4$ ),
- e) the conditions of waiting at bus stops ( $x_5$ ),
- f) accessibility to public transport ( $x_6$ )
- g) ticket prices ( $x_7$ ),
- h) directness of connections ( $x_8$ ).
- i) courtesy of drivers ( $x_9$ ),
- j) the overall quality of the information (at bus stops, in vehicles and on vehicles) ( $x_{10}$ ),
- k) readability and simplicity of memorizing timetables ( $x_{11}$ ),
- l) the opportunity to comment on the functioning of public transport ( $x_{12}$ ).

The research found that 12 of the original criteria for the quality of services can be reduced due to the application of factor analysis to two factors. The first derived factor mainly explains determinants associated with conditions of movement within the city offered in urban transport services. The variables described by this factor include the four most frequent transport demands: travel time, convenience - access to public transport, cost and safety.

The second factor is related to the additional (supplementary) areas offered by transport services, such as courtesy of drivers, access to information about the time of service delivery and readability of timetables. The system of variables forming the defined dimensions is shown in Table 1. During the study the significantly higher impact of variables was confirmed which was described by the first appointed agent to assess the quality of transport services, mainly including: ticket prices, travel time, service frequency and distance from a bus stop to the place of residence.

For further research using conjoint analysis indicated variables (criteria) were used, described by the first factor directly connected with the ongoing transport services. The validity of these variables was assessed by most respondents. The participants of the study felt that price, time, frequency, and further distance of a bus stop from home are the most important criteria for the quality of transport services.

Tab. 1 – Results of the factor analysis. Source: own calculations.

Factor 1	Factor 2
<ul style="list-style-type: none"> <li>- punctuality of vehicles (<math>x_1</math>),</li> <li>- frequency of vehicles (<math>x_2</math>),</li> <li>- travel safety (<math>x_3</math>),</li> <li>- the conditions of travel in vehicles (<math>x_4</math>),</li> <li>- the conditions of waiting at bus stops (<math>x_5</math>),</li> <li>- accessibility to public transport (<math>x_6</math>),</li> <li>- ticket prices (<math>x_7</math>),</li> <li>- directness of connections (<math>x_8</math>).</li> </ul>	<ul style="list-style-type: none"> <li>- courtesy of drivers (<math>x_9</math>),</li> <li>- the overall quality of the information (at bus stops, in vehicles and on vehicles) (<math>x_{10}</math>),</li> <li>- readability and simplicity of memorizing timetables (<math>x_{11}</math>),</li> <li>- the opportunity to comment on the functioning of public transport (<math>x_{12}</math>).</li> </ul>

Respondents were asked to evaluate a set of 12 profiles out of 36 possible variants generated by the method of orthogonal plan. Utility values that each respondent is associated with a given level of the variable set by means of a least-squares method with artificial explanatory variables.

$$\hat{Y} = b_{0s} + b_{1s}X_{1s} + \dots + b_{6s}X_{6s}. \quad (1)$$

where:  $b_{1s}, \dots, b_{6s}$  – regression parameters;  $b_{0s}$  – intercept;  $X_1, \dots, X_6$  – artificial variables.

After estimating the relative partial utility the validity of each considered variable was specified on the basis of the following formula:

$$W_j = \frac{1}{S} \sum_{s=1}^S W_j^s \quad (2)$$

where:  $W_j^s$  – relative “importance” of each attribute to the  $s$ -respondent determined according to the formula, Hair (1995):

$$W_s^j = \frac{\max_{lj} \{U_{jl_i}^s\} - \min_{lj} \{U_{jl_i}^s\}}{\sum_{j=1}^m \left( \max_{lj} \{U_{jl_i}^s\} - \min_{lj} \{U_{jl_i}^s\} \right)} \times 100\% \quad (3)$$

where:  $U_{jl_i}^s$  – partial utility  $l$  - the level of the  $j$  attribute of the  $i$  profile for the respondent  $s$  ( $s = 1, \dots, S$ ),  $lj$  - the number of levels for the  $j$  attribute and the  $i$  profile  $i = 1, \dots, n$  – profile,  $j = 1, \dots, m$  – the number of attributes,  $S$  – the number of respondents.

The results obtained during the study confirmed the findings of other authors (Pressl and Reiter, 2003; Scheiner, 2009;). In fact, all of the criteria related to the fundamental postulates of lading are significant while choosing the public transport as a means of movement within the city. The lowest percentage was obtained for criterion: time travel.

Time of travel for residents of medium-sized cities, with relatively close distances to overcome, is not a criterion of significant influence on the preferences of the inhabitants as the other analysed variables. The highest preferences identified during the research (maximum score profile) relate to services provided by the urban public transport characterized primarily by low price, high frequency of the circulation, with close proximity to the bus stop from the place of residing (Fig. 1).

**Figure 2.** The relative importance of the attributes. Source: own calculations.

In contrast, the travel time can be as long as in the case of traveling by car. Journey duration for residents of medium-sized cities is not a decisive factor for the travelers’ preferences related to the choice of public transport.

### **3.3 Proposed solutions**

With the lengthening of the average life expectancy in the European Union and the decreasing fertility rate which does not allow for a simple replacement of generations, the proportion of older people in their pre-working age is growing in most European Union countries.

The effect of these changes is a reduction in demand for transport services (a smaller percentage of children and young people of school age which is one of the main groups using public transport) and the need to provide services to meet the needs of the elderly requiring to provide a means of transport adapted to people with reduced mobility and locating stations with greater frequency (proximity to public transport) (Żochowska, 2014).

The need for such changes is now noticed in most Western European countries. On the other hand, a decline in both population density associated with the described demographic and cultural changes (resettlement of residents of cities in the area immediately adjacent to the cities, urban sprawl, suburbanization processes) causes the decrease of the economic efficiency of public transport (Scheiner, 2009; Beim, 2012).

The need to reconcile these two contradictory aspects - high quality and economic efficiency - does not allow for the fast solutions to improve the perceived quality of the services provided (often very costly). An example of technological solutions are, e.g. conducted in Germany for nearly 10 years the study aimed at exploring alternative fuels such as crude oil e.g. using hydrogen in driving city buses.

The most important are new environmentally friendly technologies limiting emissions harmful to the environment. Much more popular are innovations of an organizational nature (Masser et al., 1993; Leea and Rivasplata, 2001; Starowicz, 2010), such as:

1. The creation of intermodal information platforms that allow for individualized travel planning.
2. Bus lines on demand.
3. Taxi services (ATS), which provide services relating to transporting passengers to interchanges.
4. Additional services, e.g. buying tickets online, Wi-Fi available in public means of transport.
5. The introduction of the so-called. calm traffic zones - for example, the zone of speed limit e.g. "speed limit 30", the residential area, shared space or cycle streets.
6. Systems which reduce the movement of cars in city centres – e.g. Park & Ride (P + R).
7. The introduction of charges for the use of roads or streets (Road Pricing), which are treated as “environmental tax” aimed at reducing the environmental burden caused by the movement of cars or so called rationalizing tax (Congestion Charge Zones), whose goal is to bring to the limited use of the common good which is “the use of a road”.
8. The development of bicycle parking facilities, including multi-story car parks.
9. Preference in the purchase of housing in areas immediately adjacent to the railway interchanges.
10. Concentration of residential areas along public transport corridors - common planning of urban development and transport.
11. Transport demand management.

## 4 CONCLUSION

According to the report (European Commission, 2013) it is estimated that urban transport generates costs of 230 billion Euros in 27 EU capital cities (without Zagreb). The main components of these costs are: congestion (80 billion EUR), accidents (80 billion EUR) and noise (40 billion EUR). The intensive growth of the automotive industry, accompanied by lack of local public transport investments, has resulted in many less affluent countries to a decline in the attractiveness of public transport, limiting its availability, regularity and frequency of running vehicles. The experience of Western European countries indicate that sooner or later the governments of cities in Poland will be forced and very often take actions today, which aim is to reduce car traffic in city centres and to increase the interest in the movement of urban public transport.

The effectiveness of actions taken, however, is conditioned by the complexity of applied solutions suited to the actual needs of the residents. It is therefore important to research on the preferences of the residents. The problem of many cities, beside the surge in the number of cars, it is also a significant increase in road freight transport, which puts a burden on municipal systems. According to the Energy & Transport in Figures 2006, European Commission Luxembourg, 2007, the number of private cars per 1,000 inhabitants increased from 15 in 1970 to over 400 in 2012.

Easy transportation within cities is also impeded due to housing development in suburban areas and placement outside concentrated urban housing large shopping centers. The solution to traffic problems of cities should be adequate to the implementation of transport policy allowing to increase the competitiveness of public transport and consequently reducing congestion, noise and pollution while increasing security.

Public transport except that reduces traffic is more environmentally friendly than individual transport by car. Due to the constantly decreasing interest in this form of travel, it is important to take proper measures to encourage residents to use this kind of transport. It is also vital to monitor the quality of service offered by the public transport services.

The presented results of the modelling transportation preferences of urban residents with the application of the methods of multidimensional statistical analysis allowed to identify the comprehensive travelers' preferences. From a practical point of view, these studies are significant because of the possibility of simultaneous comparison of many individual preferences of travelers. It is also important opportunity to introduce the proposed methods to a comprehensive and more complex modelling of transport behavior.

The results of carried out studies clearly indicate that price, frequency and distance from the main stops are the key factors affecting the assessment of the quality of public transport in medium-sized cities. Travel time due to the rather short distances turned out to be a less important factor. It will be certainly more important aspect in the case of residents of large cities, more congested and less efficient in communication.

## **HOW DO WOMEN AND MEN FEEL SOME ASPECTS OF SATISFACTION AND LOYALTY IN BANKING SECTOR? A CASE STUDY FROM THE CZECH REPUBLIC**

*Anna Chochořáková, Lenka Gabčová*

### **Abstract**

The aim of our research was to investigate the relationship between gender and major attributes of satisfaction and loyalty of the banking clients. In this context, at the same time it was investigated whether there are statistically significant differences between the genders depending on age and education. The banks' customers' satisfaction research was conducted through a questionnaire investigation in the Czech Republic in 2014 on a sample of 459 respondents, of which 44% were men and 56% were women. The results of our research pointed to the fact that there are some differences in the attitudes and opinions of men and women in the area of satisfaction and loyalty of the banking customers. More women believe that the bank staff has a genuine interest to understand their financial needs. In our research, women have more often reported that their bank's staff would explain them the advantages and disadvantages of bank products that are of their interest. It was also found out that women are more loyal to their banks than men. Men and women thus perceive some factors that determine their level of satisfaction in different ways. For this reason in banking practice it is necessary to correctly assess the different trends and apply them to the customer care system.

*Keywords: satisfaction of banking customers, loyalty, gender approach, factors of customer satisfaction*

JEL Classification: G21

## **1 INTRODUCTION**

Commercial banks perceive retail clients as a particularly interesting segment due to the subjective preferences of clients, such as their willingness to accept higher prices of products in case of economic distress, relative disinterest in their own money, laziness, preference of other life values and lower financial literacy. (Belás, 2005)

Compliance with the consumers' needs and requirements (Bilan, 2013), comprehensive customer care and the bank customers satisfaction is currently in the centre of attention of researchers and bankers, as it represents an important marketing variable for most of the companies, especially those working in the most competitive markets (Munari, Ielasi, Bajetta, 2013; De Matos, Henrique, and De Rosa, 2013).

The current theoretical research on the satisfaction of the bank customers deals with various attributes of this process. Our aim is to find out whether there are significant differences in the satisfaction of bank customers from the gender point of view.

## **2 THEORETICAL BACKGROUND**

Customer satisfaction is an important factor in the performance and competitiveness of banks (Adolpson, Eklóf, Parmler, 2013; Choudhury, 2013; Keisidou, Sarigiannidis, Maditinos, and Thalassinou, 2013) because the bank business depends substantially on the quality of the customer service and the overall satisfaction of customers. (Chavan and Ahmad 2013)

Chavan and Ahmad (2013) have defined eight most important attributes of satisfaction: paying individual attention to each client, personnel behavior inducing customer trust, attractive bank equipment, zero fees for issuing checks, zero error records, the possibility of online banking, security of transactions, helpful staff and its readiness to answer to customer requirements regardless of occupancy.

Some authors declare that the satisfaction of bank customers is determined by their age (Baumann, Elliott and Burton, 2012; Tesfom, and Birch, 2011). On the contrary, Belás, Cipovová and Demjan (2014) argue that the overall level of satisfaction of banking clients in the Czech Republic and Slovakia was not determined by their gender, age or education.

Many authors agree that customer satisfaction has a strong positive impact on customer loyalty (for example, Seiler, Rudolf, and Krume, 2013) and mediates the impact of service quality on loyalty (Karapete, 2011). Understanding of customer loyalty requires understanding of customer satisfaction first (Fraering, and Minor, 2013). Consumers don't want to play in any games, if they feel that anything goes wrong, they go away and choose another supplier (Bilan, 2013)

The high quality of banking services determines further additional purchases of client as well as his loyalty, which means that a satisfied customer provides information about his satisfaction and future bank clients from his own environment: family, friends and colleagues. (De Matos, Henrique, and De Rosa, 2013; Choudhury, 2013). According to Terpstra and Verbeeten (2014) satisfied customers tend to be loyal and willing to purchase more of firm's services at higher prices.

Comparison of genders in the area of the satisfaction of bank customers is not very widespread topic of scientific researches. Among the renowned scientific journal databases only two works that deal with this topic were discovered by us. The satisfaction of bank customers is also determined by their gender (De Matos, Henrique, and De Rosa, 2013; Karapete, 2011). De Matos, Henrique, and De Rosa (2013) suggest that women are more likely to remain loyal to their bank, when compared to men, which can be attributed to the fact that men are more willing to take risks than are women and, socially, men are expected to behave in this way, in agreement with the social role theory. Karapete (2011) investigates customer satisfaction as a mediator of the effects of service environment, interaction quality, empathy, and reliability on loyalty. The results reported in his study suggest that all service quality dimensions have significant positive impacts on customer satisfaction. Interaction quality is the most important determinant of customer satisfaction, followed by service environment, reliability, and empathy. The impacts of empathy and reliability on satisfaction are higher among female customers than male customers. The results do not lend credence to gender as a moderator in the relationship between: service environment and satisfaction, and interaction quality and satisfaction (equally important for both male and female).

We think that it may be interesting and challenging enough to explore bank customers' satisfaction by gender and carry out a detailed analysis among men and women also in relation to the age and education.

### **3 RESEARCH AIM, METHODOLOGY AND DATA**

The aim of the research was to investigate the relationship between gender and major attributes of the satisfaction and loyalty of the banking customers. In this context in the same time there was investigated whether there are statistically significant differences between the genders depending on the age and education.

Bank customer satisfaction research was conducted through a questionnaire survey in the Czech Republic in 2014 on a sample of 459 respondents, of which 44% were men and 56% were women. The age structure of those respondents was as follows: 39% of respondents were aged under 30 years, 44% were aged from 31 to 50 years and 17% of them were customers over 50. The education level of respondents was as follows: 3% had primary education, 54% had secondary education and 43% were university educated bank customers.

The results of the study of De Matos, Henrique, and De Rosa (2013), Karapete (2011) in the context of the conclusions according to Baumann, Elliott and Burton (2012), and Tesfom and Birch (2011) have inspired us to formulate the following hypotheses:

H1: Men and women feel differently the rate of the personal knowledge and recognition by the banking staff. There are statistically significant differences between the genders and within the selected structure (when comparing women and men by age and type of education).

H2: Men and women feel their own importance for the bank differently. There are statistically significant differences between the genders and within the selected structure (when comparing women and men by age and type of education).

H3: Men and women perceive a genuine interest of the bank's staff to understand their financial needs differently. There are statistically significant differences between the genders and within the chosen structure (when comparing women and men by age and type of education). Women to a greater extent believe that the bank staff has a genuine interest to understand their financial needs.

H4: Men and women perceive differently the approach of the bank staff. There are statistically significant differences between the genders and within the chosen structure (when comparing women and men by age and type of education). Women to a greater extent feel that the bank staff will explain the advantages and disadvantages of the product in which they are interested.

H5: There are statistically significant differences between the genders and within the chosen structure (when comparing women and men by age and type of education) in the field of loyalty. Women to a greater extent state that, when they saved the money, they would put them to their bank.

Established scientific hypotheses in each table were examined through Z Test (available at: <http://www.socscistatistics.com/tests/ztest/Default2.aspx>). Z Test is a concept of statistics which compares means of two populations. P-value less than 5% leads to the rejection of the null hypothesis. Part of the quantitative analysis is the use of indicators and descriptive statistics such as weighted arithmetical average and the percentage figures.

## **4 RESULTS AND DISCUSSION**

According to the results of our research, the overall satisfaction of clients of commercial banks was at the level of 66.23% in 2014, and 16.34% of the customers report a negative attitude and 17.43% of respondents could not decide.

Similar findings were also found in another study in the year 2012 in the Czech Republic (Belás, Burianová, Cipovová, Červenka, 2013) and in Slovakia in 2012 (Belás, Holec, Homolka, 2013).

Berry (2005) states that the customer wants to be highly rated in his bank. The bank can fulfill this objective by getting to know its customers personally as it gives the client a feeling of importance, also if the bank staff have a perfect overview of client's activities in the bank, if the client is not surprised by the bank's pricing policy, if the client feels that there is helpful,

attentive and polite staff at a branch of the bank, and which can minimize errors in procedures. Author expressed his concern about the fact that in the research, which took place in the Great Britain, over 40% of bank customers are unknown for the bank and being treated like strangers; in the age group 18-29 this figure even raised to 60%. What is the situation in the Czech Republic 10 years later?

In Table 1 there are presented the results of three surveys on personal knowledge of bank customers by bank staff separated by gender and by the chosen structure within each gender group.

The results of our research have indicated an interesting trend. Even though women place greater emphasis on the satisfaction factor of convenient and friendly service in a bank’s branch, at the same time they frequently stated that they feel that the bank personal doesn’t know them personally. This trend was statistically significant when there were compared women over 30 years old and university-educated women with the men in the same category.

Hypothesis 1 was partially confirmed.

The overall rate of personal knowledge of clients is relatively low, as only 34.97% of men and 31.25% of women reported that the bank staff knows them personally. Men under 30 years old reported the lowest perceived level of personal knowledge of 22.58%. When our results are compared with the results of Berry (2005), it is clear that commercial banks have significant reserves and room for improvement in this area. It is obvious that intensive expansion of credit cards and electronic banking has reduced the number of visits of customers to the bank offices, but the fact that the banks know their customers poorly makes them miss out on important sales opportunities.

Tab. 2 – Feelings of the client when communicating with bank’s staff. Source: own source.

<i>When visiting a bank, I feel that I am an important client for them.</i>	Men < 30 years > 30 years University degree Other education in %	Women < 30 years > 30 years University degree Other education in %	p-value

	34.12	26.85	0.27572
	29.59	35.81	0.31250

After receiving answers to this question, there have not been detected any significant differences in the responses of our respondents. Hypothesis 2 was rejected.

Our results highlight the fact that only 36.07% of men and 37.89% of women feel that they are an important clients for their banks.

	36.47	22.22	<b>0.02926</b>
	31.63	33.78	0.72634

According to our results, women compared with men more believe that the bank employees have a genuine interest to understand their financial needs. Statistically significant differences were found when comparing the whole set (p-value=0.00960) and also in the category up to 30 years old (p-value=0.00080) and in the category with primary and secondary education (p-value=0.03078). Hypothesis 3 was confirmed.

According to our results, 37.16% of men and 49.61% of women in the Czech Republic thought that bank employees have a genuine interest in understanding their financial needs. In this context Berry (2005) states that bank staff from the banks’ branches is often perceived as unhelpful and material, whereas the bank’s customers expect a friendly approach. Sometimes even the bank staff is unable to answer basic questions and referring customers to address those queries to the experts, however, those are not always available in the moment.

In our research, women have more often reported that the bank staff would explain them the advantages and disadvantages of bank products that they are interested in. A statistically significant difference was found in the categories of respondents with higher education.

Hypothesis 4 was rejected by the statistical significance, but there was found a hint of a trend that was defined in our hypothesis.

The results of our research in the field of communication of customers with the bank employees provided in Tables 1, 3, 6 show that women give more importance to other factors than men. It could be therefore agreed with opinion of Karapete (2011), which states, that his findings may be attributed to the fact that women are relationship-oriented and attach more importance to social interactions with customer-contact employees providing them with specific information about bank services and dealing with their requests and problems effectively.

The following table shows the results of research in the field of the banking customer loyalty.

Tab. 5 – Loyalty and purchasing of other products. Source: own source.

<i>When I save up some money, I put it to my bank.</i>	Men < 30 years > 30 years University degree Other education in %	Women < 30 years > 30 years University degree Other education in %	p-value
1. Yes	55.74	64.45	<i>0.06576</i>
	58.06	70.97	0.07840

3. I do not know	16.39	14.45	0.57548
	14.52	10.48	0.42372
	17.36	18.18	0.86502
	15.29	8.33	0.13104
	17.35	18.92	0.75656

In our research, women have more often stated that they would be willing to make a deposit to their bank in comparison with men. Hypothesis 5 was rejected.

Even though this hypothesis has been rejected, there was found a trend indication that women tend to be more loyal than men with respect to their banks. The value of the test criteria (p-value=0.06576) was fluctuating at the critical line. In all defined social groups, women showed a higher degree of loyalty and a greater tendency to create deposits in their own banks.

## 5 CONCLUSION

The results of our research pointed to the fact that there are some differences in the attitudes and opinions of men and women in the area of satisfaction and loyalty of the banking customers.

More women believe that a bank staff has a genuine interest to understand their financial needs. In our research women have more often reported that their bank's staff would explain them the advantages and disadvantages of bank products that are of their interest. It was also found out that women are more loyal to their banks than men.

Men and women thus perceive some factors that determine their level of satisfaction in different ways. For this reason in banking practice it is necessary to correctly assess the different trends and apply them to the customer care system.

Our study has some limitations, of course, but it can be a good inspiration for bank managers to take appropriate actions to improve the financial performance of the bank through the growth of customer satisfaction and customer loyalty.

Our future research would be focused on quantifying dependence between additional purchases of the bank products and services and the satisfaction and loyalty of banking customers. The gender approach would be also a part of this research.

## **SAVING VERSUS INVESTING IN THE LONG TERM**

*Bozena Chovancova, Peter Arendas*

### **Abstract**

A lot of theories about financial markets have been challenged during the last two decades. A lot of financial experts and analytics focused their attention on the effectiveness of long term investing in relation to the pension systems that are by a large part dependent on the development of capital and especially stock markets. The global financial crisis has resulted not only into a slump of the economic activity but also into collapse of capital markets which has negatively affected the yields of pension funds. The aim of this article is to evaluate the long term effectiveness of saving in comparison to index investing, using the cost averaging strategy. Some specifics of the development of capital markets in various geographical areas have led us to focus on three main financial markets: the USA, Japan and Germany. The analysis shows that the indexing investment strategy supported by the cost averaging effect is superior to simple saving in the long run.

*Keywords: interest rates, index investing, long term investment strategies, cost averaging effect,*

JEL Classification: G00, G10, G11

### **1 INTRODUCTION**

Evaluation of effectiveness of long term saving and investing has been the topic of many important publications, scientific papers and analytical works. Some of the authors focus on the long term investment strategies, mostly on the buy & hold and cost averaging strategies. Other authors pay closer attention to the problematics of correct market timing or optimal stock picking strategies.

A very important author who focuses on the problematics of investing is Siegel (2014) who analysed the whole history of the American stock market. He has proven that long term investing in stocks is effective despite of some significant market crashes. Edelson (2007) analysed the long term effects of the cost averaging strategy and he came to the same conclusion as Siegel. Very interesting were studies by Malkiel (2010) and Bogle (2010) who tried to create an optimal portfolio. They concluded that index investing is on average as effective as active investment strategies in the long term. A well-known author is also Graham (2007) who is one of the most important supporters of the long term investing.

A detailed analysis of selected long term stock market investment strategies as well as the comparison of passive and active investment strategies was conducted also by other authors. For example Pastor and Stambaugh (2012) focused on the declining effectiveness of actively managed investment funds. French (2008) came to conclusion that “the typical investor would increase his average annual return by 67 basis points over the 1980-2006 period if he switched to a passive market portfolio”. Lye (2012) analysed the differences between growth and value stocks. Cambell, Polk and Vuolteenaho (2010) analysed systematic risks of stock investing.

## **1.1 Methodology**

The effects of long term saving and investing on the time horizon of the last 30 years will be examined. The American S&P 500 stock index will be used, as the American stock market is the best liquid one, with a well-documented history. It comprises of a widely diversified portfolio of stock companies across all of the sectors of the U.S. economy and it reflects the relation between the stock market and the U.S. economy very well. It is very close to the theoretical concept of the optimal portfolio. The long term investing in S&P 500 will be compared to the long term regular saving using FED main interest rates plus 1% premium.

Another stock market chosen for the analysis is the Japanese stock market represented by NIKKEI 225 stock index. Europe will be represented by Germany and its benchmark stock index DAX 30. Similarly to the U.S. case, there will be main interest rates of the Bank of Japan and the Deutsche Bundesbank (the European Central Bank respectively) plus 1% premium used for calculation of the performance of the regular long term saving.

The analysis is based on following assumptions:

- 1) Only approximately 25% of portfolio managers are able to beat the market benchmark. Most of them manage hedge funds that often undergo significant risk. It is very hard for pension funds to beat the benchmark because of various regulations that limit them. Therefore we will assume that the aim of the pension funds is not to beat but the benchmark but to reach returns similar to benchmark.
- 2) The investor invests regular amount of 100 USD per month into a pension fund that tracks the stock index (S&P 50, Nikkei 225 or DAX 30) and he saves 100 USD per month with a monthly remuneration at the key interest rate (FED, BOJ, DBB/ECB) valid at the start of the month plus 1% premium. The yields are reinvested regularly.
- 3) The stock investments are made on the monthly basis using stock index value on the first day of the calendar month. All dividends are reinvested.
- 4) The savings are remunerated using the key interest rates plus 1% premium. The premium simulates the margin offered by commercial banks to the depositors. The margin is floating according to the current market situation in real life (for example the FED key interest rate was 17,39% back in 1981 and the interest rates offered to the depositors by commercial banks were over 19%.), but we used a constant 1% margin in order to keep things simple
- 5) The analysis abstracts from the transaction costs. Fees paid to the broker or fees paid to the bank are not taken into account, as the fees were changing over time and it is impossible to quantify them properly.
- 6) The analysis also abstracts from taxes.
- 7) The results are evaluated on the nominal as well as on the real basis.
- 8) The currency used in the analysis is USD. Only one currency is used in order to enable the comparison between individual countries. The assumption is that there is a constant purchasing power parity and the changes in exchange rates are driven by inflation differential solely, so that the results in different countries can be compared more easily.
- 9) The whole 30 year time period is evaluated (1985 – 2014) as a whole and also divided by decades (1985 – 1994, 1995 – 2004, 2005 – 2014).
- 10) The investing on a regular basis leads to the cost averaging effect.

As a result, the long term effectiveness of investing and saving in three different countries can be compared.

## **2 THE EFFECTIVENESS OF SAVING AND STOCK INDEX INVESTING IN THE USA – 30 YEAR TIME HORIZON**

The first time period (1985 – 1994) was preceded by significant changes on financial markets that were a consequence of the monetary crisis in the 70's. The crisis led to the cancelation of the convertibility of USD for gold and a strong depreciation of USD. The debt crisis in early 80's was related to instability of the financial system that resulted into a strong growth of inflation and interest rates. As a result saving was as successful as stock investing, if not even more (depending on the time period).

Tab. 1 – The comparison of saving and stock investing – USA. Source: own calculations

		1985 - 1994	1995 - 2004	2005 - 2014	1985 - 2014
monthly investment		100,00	100,00	100,00	100,00
cumulative investment		12 000,00	12 000,00	12 000,00	36 000,00
final balance	deposit account	16 772,46	14 943,35	13 156,94	68 348,07
	stock investment	17 957,83	15 642,17	19 081,45	126 199,40
nominal return	deposit account	4 772,46	2 943,35	1 156,94	32 348,07
	stock investment	5 957,83	3 642,17	7 081,45	90 199,37
cumulative nominal yield	deposit account	39,77%	24,53%	9,64%	89,86%
	stock investment	49,65%	30,35%	59,01%	250,55%
cumulative inflation for the period		41,94%	26,97%	23,76%	123,04%
final balance - purchasing power (start of the period money value)	deposit account	11 816,58	11 769,20	10 631,01	30 643,86
	stock investment	12 651,70	12 319,58	15 418,11	56 581,51

The saving yielded 4 772 USD during the first decade. The final sum on the deposit account was 16 772 USD which means cumulative yield of almost 40%. The index investing brought yields of 5 957 USD or nearly 50%. This decade is typical for its high levels of inflation. The cumulative inflation reached up to 42% during the time period from 1985 to 1994. It means that saving on the deposit account resulted in a negative real return. The real return of the index investing was positive but only marginally.

The second decade (1995 – 2004) was characterized by a boom of stock investing thanks to the arrival of new technologies and the development of so called “internet economy”. The growth of the economy and the stock markets was supported also by the FED that was decreasing interest rates. Lower interest rates resulted in an expansion of margin trading. Also the inflation decreased significantly compared to the previous time period. The stock investing was able to outperform saving significantly in the late 90's. People who went on pension during those years had secured high rents. But the situation changed dramatically after 2000 when the internet bubble busted. The collapse of the stock markets resulted in huge losses for investors, including the pension funds. The situation is shown by Figure 1.

As Table 1 shows, the final results of saving and stock investing were similar also during the second decade. The deposit account yielded 2 943 USD and the index investment yielded

3 642 USD. Although the cumulative inflation was significantly lower compared to the first decade, the nominal returns were significantly lower as well and therefore the real returns were even worse in the second decade than in the first one. The deposit account finished with a slightly negative real return again. The index investment had only a miniscule positive real return again.

Fig. 1 – The nominal return of the deposit account and index investments – Japan. Source: own calculations

The third decade brought a significant between the performance of saving and index investing, despite the global financial crisis. The main reason is the monetary policy of the FED that has adopted measures such as nearly-zero interest rates policy and quantitative easing very quickly after the full outbreak of the financial crisis. The aim of these policies was to support the real economy and the financial markets. The biggest impact is able to see in the case of the stock markets that started to grow strongly.

The deposit account yielded only 10% while the index investments yielded more than 59% between 2005 and 2014. The disappointing results of saving were caused by the policy of extremely low interest rates that lasted for the bigger part of this time period. Despite low levels of inflation, the real yield of saving was negative once again. On the other hand index investing recorded a real yield over 28%.

A lot of things happened in the U.S. economy during the whole time period (1985 – 2014). Although there were some major stock market slumps, the analysis shows that the results of stock index investing were far superior to saving. The saving return was 32 348 USD while the investing return was 90 199 USD. In percentage terms the deposit account yielded 90% and the stock index yielded slightly over 250%. But the real yields are significantly lower due to the inflation that climbed up to 123%. The real yields of the deposit account were –15% and the real yields of the stock investing were 57%.

### 3 THE EFFECTIVENESS OF SAVING AND STOCK INDEX INVESTING IN JAPAN – 30 YEAR TIME HORIZON

Absolutely different results are shown by the comparison of saving and stock investing in Japan over the same time period. The 70's and 80's were characterised by very strong economic growth. As a result investors started to pour their capital into Japan and the Japanese stock market started to grow as well. The bull market resulted into a stock bubble in the early 80's. Also the interest rates were quite high during this time period. The collapse of the stock market bubble resulted in huge losses. This is why the saving was significantly more successful compared to stock investing during the first time period (1984 – 1995).

The calculations show that saving recorded 25% nominal yield while stock investing yielded -3,84% due to the collapse of the Japanese stock market. The inflation reached almost 16% during this time period. It means that the real yield of the deposit account was almost 8% and the real yield of the stock investing was -17%.

Tab. 2 – The comparison of saving and stock investing – Japan. Source: own calculations

		1985 - 1994	1995 - 2004	2005 - 2014	1985 - 2014
monthly investment		100,00	100,00	100,00	100,00
cumulative investment		12 000,00	12 000,00	12 000,00	36 000,00
final balance	deposit account	14 999,10	12 687,56	12 673,59	45 884,22
	stock investment	11 538,89	9 979,21	18 090,53	43 863,32
nominal return	deposit account	2 999,10	687,56	673,59	9 884,22
	stock investment	-461,11	-2 020,79	6 090,53	7 863,32
cumulative nominal yield	deposit account	24,99%	5,73%	5,61%	27,46%
	stock investment	-3,84%	-16,84%	50,75%	21,84%
cumulative inflation for the period		15,77%	-0,59%	3,30%	18,88%
final balance - purchasing power (start of the period money value)	deposit account	12 955,95	12 762,86	12 268,72	38 597,09
	stock investment	9 967,08	10 038,44	17 512,61	36 897,14

Similar results were achieved also during the second time period (1995 – 2004). The Bank of Japan pushed its key interest rates close to the zero level and it started a quantitative easing in order to avoid deflationary pressures and kick-start the economy and stock markets. The cheap money policy negatively affected the results of the deposit account that recorded nominal yield of only 5,73%. On the other hand the efforts of the Japanese central bank and government were insufficient and the bad performance of the stock market continued. The nominal yield of the stock index investing was -16,84%. The cumulative inflation was -0,59% for this time period. The deflation helped to improve the real yields slightly, to 6,36% and 16,35% respectively. The abovementioned development is captured also by Figure 2.

A little better results were achieved during the third time period (2005 – 2014). The positive results of the monetary policy started to show up in the form of reflation. The saving yielded 5,61% which is almost identical to the previous time period. On the other hand the investing yielded 50,75%. But it is important to note that the positive result of the stock index investing was achieved only due to the very good stock market performance in 2013 and 2014. The real yields were 2,23% and 45,93% respectively.

The analysis of the whole time period shows that the Japanese investor (a potential pensioner) would have better returns from saving. The deposit account yielded 27,46% while the stock index investments yielded only 21,84%. Although the cumulative inflation was only 18,88%, the inflation adjusted yields are not overly optimistic. The real yields are 7,22% and 2,49% respectively. It means that both alternatives were merely able to beat the inflation. Another problem is the high level of the Japanese government debt that is over 250% of GDP. The Japanese problems with financing the pension system will grow. Moreover the yields of the deposit as well as the stock market prove to be ineffective for capitalisation pension schemes.

Fig. 2 – The nominal return of the deposit account and index investments – Japan. Source: own calculations

#### **4 THE EFFECTIVENESS OF SAVING AND STOCK INDEX INVESTING IN GERMANY – 30 YEAR TIME HORIZON**

Germany is an economic leader of the European Union and how the analysis shows (Table 3) the returns from its financial markets are able to beat the U.S. financial market returns on a regular basis.

There were higher interest rates during the first time period (1985 – 1994) therefore the deposit account yielded 41%. The stock index investing yielded 52%. The success of the German stock market was supported also by a restructuring of the German economy that took place in the first half of the 90's. But the inflation was relatively high, its cumulative value is 27,91%. It means that the real yield of saving was 10,6% and the real yield of investing was 18,96%.

The cheap money policy and low interest rates resulted in significantly worse results for the saving strategy in the second time period (1995 – 2004). The nominal yield was only 22,16%. The German stock market experienced a very strong growth in the late 90's followed by a stock market collapse in the early 2000's. As a result the stock investments yielded only 14,33% which is even less than the deposit account. The inflation decreased approximately by a half, to 15,68%. As a result the real yield of saving was 5,6% and the real yield of investing was -1,17%.

The third decade (2005 – 2014) was affected by the global financial crisis as well as by the European debt crisis. The European Central Bank decreased the interest rates in order to support the economy. As a result the deposit account yielded only 12,16% during this decade. The stock market collapsed in 2008 but the crash was followed by a strong bull trend that resulted in 55,62% yields for the stock investing strategy. The cumulative inflation was 15,89% during this time period which means that the real yield of saving was -3,22% and the real yield of investing was 34,28%.

Tab. 3 – The comparison of saving and stock investing – Germany. Source: own calculations

		1985 - 1994	1995 - 2004	2005 - 2014	1985 - 2014
monthly investment		100,00	100,00	100,00	100,00
cumulative investment		12 000,00	12 000,00	12 000,00	36 000,00
final balance	deposit account	16 978,08	14 659,70	13 458,81	65 767,81
	stock investment	18 259,06	13 719,27	18 674,92	136 909,00
nominal return	deposit account	4 978,08	2 659,70	1 458,81	29 767,81
	stock investment	6 259,08	1 719,27	6 674,92	100 909,00
cumulative nominal yield	deposit account	41,48%	22,16%	12,16%	82,69%
	stock investment	52,16%	14,33%	55,62%	280,30%
cumulative inflation for the period		27,91%	15,68%	15,89%	71,47%
final balance - purchasing power (start of the period money value)	deposit account	13 273,46	12 672,63	11 613,44	38 355,29
	stock investment	14 274,93	11 859,67	16 114,35	79 844,29

Fig. 3 – The nominal return of the deposit account and index investments – Germany. Source: own calculations

The evaluation of the whole 30-year time period shows, that the stock investing was clearly superior to saving. The development of nominal returns of saving compared to investing is shown by Figure 3. The yield of saving was 82,69% while the yield of investing was 280,3%. The cumulative inflation was 71,47%, thence resulting that the real yield of saving was only 6,54% while the real yield of investing was 121,79%.

## **5 THE COMPARISON OF EFFECTIVENESS OF SAVING AND INVESTING IN DIFFERENT COUNTRIES**

Although the financial markets are globalized we can see significant differences between results of saving and stock index investing in different countries. Especially the 30-year time horizon fully shows the magnitude of the differences.

When we compare the savings, the biggest nominal returns were achieved in the USA, followed by Germany and Japan. The final account balances were 68 348,07 USD in the USA, 65 767,81 in Germany and 45 884,22 in Japan. The results of saving in Japan are poor due to more than two decades of extremely low interest rates.

Even bigger differences can be seen when comparing results of the stock index investing in particular countries. The best results were achieved in Germany where the final balance reached up to 136 909. The final balance was slightly lower in the USA (126 199,40). By far the worst results were recorded in Japan where the two decades of stock market stagnation resulted in a final balance of only 43 863,32 which is really a very disappointing result.

Fig. 4 – Inflation adjusted final account balances (purchasing power of 1985). Source: own calculations

But the view on the results changes significantly when the inflation is taken into account. Figure 4 shows inflation adjusted final balances. For example the final balance of the U.S. deposit account is 68 348,07. But 68 348,07 in 2014 is worth only 30 643,86 from 1985. The cumulative inflation was 123,04% in the USA, 71,47% in Germany and only 18,88% in

Japan. It means that although the nominal results were significantly better in the USA and in Germany, the differences are much smaller in the real values. As a result the saving in Japan and in Germany is comparable and the worst results were achieved by saving in the USA. By far the best results were reached by investing in Germany where the inflation adjusted final balance grew up to the 80 000 level. In the USA it is 56 581 and in Japan only 36 897.

## **6 CONCLUSION**

The analysis shows that investing is superior to saving in the long term. Although there were some huge market crashes after 2000 and 2008, the results of investing were significantly better compared to saving. There were only a couple of short time periods when the deposit account balance was higher than the investment account balance. Those time periods lasted for only a couple of months right after the huge market collapses. The only difference is Japan where the results of saving and investing were almost equal. This is an important conclusion for various pension schemes.

We used a simple indexing strategy. The results of our study have confirmed the conclusions of J.C. Bogle (2010) who says that an easy indexing strategy is able to outperform most of the actively managed portfolios that are able to beat the market only occasionally, not regularly. In other words, the indexing strategy may be negatively affected by the market turbulences but it is very effective over long time periods. Also J. Siegel (2014) says that the indexing strategy needs “stocks for the long run”. Although his studies usually use minimum time horizons of 7-10 years for stock investments, our analysis was based on 10 and 30 year time horizons. Our results show that the long term effects of the indexing strategy were further supported by the cost averaging effect. The regular monthly investments enabled us to mute the negative effects of the market cycles. We were able to buy the assets at lower prices during the market slumps, which led to a decreased average cost. Although there is some potential for the fund managers to beat the benchmark using some active investment strategies, the praxis shows that the vast majority of them are unable to do it.

It is also important to note that although the German stock market performed well over the analyzed time period, there is a real threat that it will have to face some headwinds in the coming years due to the problems of the European economy related to the still unresolved debt crisis. According to Sipko (2014) the European debt crisis was caused by a mixture of internal and external imbalances. Some of the economists talk about the possibility that the economic situation in Europe may be very similar to the Japanese lost decades in the coming years. In this case we should expect worse results of the European stock markets in the near future. But as the analysis shows the stock market returns are superior to saving. Sometimes it only takes a little more time.

## **CAPITAL STRUCTURE DETERMINANTS AND HUMAN CAPITAL: POOLED, PANEL AND DYNAMIC PANEL ESTIMATIONS**

*Agha Jahanzeb, Norkhairul Hafiz Bajuri, Aisha Ghori*

### **Abstract**

This study provides empirical evidence about capital structure determinants and human capital in developing markets by studying non-financial Pakistani firms. The study demonstrates that the capital structure of Pakistani firms is shaped by same factors as suggested by developed markets, i.e. firm size, profitability, tangibility, age, non-debt tax shield, uniqueness and liquidity. More importantly, human capital also remained highly significant with total debt. Results of Generalized Method of Moments (GMM) also showed nearly same kind of significant findings.

*Keywords: capital structure, human capital, debt financing, leverage, panel data estimation*

JEL Classification: F65, G00, G30, G31, G32

### **1 INTRODUCTION**

For all business organizations, decisions about the capital structure are very important. In general, in the corporate business form, it is the management's job to make the decisions regarding the capital structure in a manner that the value of the firm is maximized. Though, maximization of the value of firm is a difficult task as it entails the selection of equity and debt securities in an equal proportion taking into account the different benefits and costs attached with these securities. If an incorrect decision is made in the process of selection it may result in the firm's financial distress and ultimately in bankruptcy. The association between decisions of capital structure and firm value is being widely studied in the last few decades. Usually, a firm is able to acquire funds through the financial market in order to finance its investments in the two manners: by means of issuing corporate stocks (equity market) or by means of issuing a debt instrument (credit or bond markets). In this regard, the expression "Capital Structure" denotes the manner in which a firm finances its investments by means of some combination of debt and equity. Although, equity and debt are not similar in nature, they complement one another as the sources of finance for projects of corporate investment. Therefore, for each investment, the trick is to determine the optimum combination of both. If a corporation possess debt in large amounts, it might overreach its potential to overhaul the debt and can turn out to be susceptible to business downturns and variation in rates of interest, and hence would be sighted to be financially perilous. Conversely, equity in large amounts weakens the interest of ownership, exhibits the firm to external control, and generally specifies that the business is ineffectively utilizing its cash to acquire business assets. This might be upsetting for investors, as it signifies a smaller amount of profits being dispersed to them.

It is indicated by Wald (1999) that institutions might considerably assert an influence over the capital structure decision of firms and that monitoring and agency problems, whereas staying in all countries might generate different results. Although the greater part of the research outcomes is being obtained from the expertise of the developed economies that encompass various institutional similarities (Rajan & Zingales, 1995; Wald, 1999; Bevan and Danbolt,

2002), diminutive work is being done for the purpose of advancing our knowledge about capital structure in developing countries that encompass dissimilar institutional structures.

Capital structure possesses a puzzling nature (Titman, 1984), which still remains the same. Hence, this research attempts to further explore the capital structure determinants and investigates the matter by employing human capital into it. Human capital is considered to be the most important part of any organization. Therefore, it is important to see what impact it has on leverage and external financing and how firms deal with the leverage by spending more on human capital. Furthermore, this study employs the data of non-financial firms of Pakistan. Studies on this issue in Pakistan are still rare and that even present dissimilar results. Not only this, the study investigates the relationship of firm age, uniqueness and human capital with leverage ratio for the first time. The results of this study will also help understand the nature of capital structure in other developing countries as well.

## **2 LITERATURE REVIEW**

An essential matter in corporate finance involves understanding of how firms choose their financing choices and it is apparent that there is no consensus on theories that explains a firm's perfect capital structure (Seifert & Gonenc, 2010). Modigliani and Miller (1958) initiated the first study on capital structure which hashes out that the capital structure is immaterial in a corporate world without taxes, transaction costs or other market imperfections.

### **2.1 Modigliani-Miller Theorem**

This ground-breaking study was presented by Modigliani and Miller (1958) on an assumption that there is the existence of market perfection in capital market. Therefore, the market operates without transaction costs and bankruptcy costs, and information is available for everyone in the market. Modigliani and Miller (1958), in other words, asserted that financing decisions of firms are undertaken with identical interest rate and without tax. As a result, cost of equity is same for firms which are, both, leveraged and non-leveraged. For the non-leveraged firm, premium is included for financial risk. Ultimately, these assumptions are pointing out that value of the firm is independent to its capital structure. Modigliani and Miller (1958) first began this groundbreaking work on capital structure in the field of Corporate Finance. According to MM Theorem, in perfect capital markets no impact of leverage can be seen on firm value. This theorem documented that firm's value is not affected by debt-equity ratio.

### **2.2 Trade-Off Theory**

Trade-off theory by focusing on cost and benefit analysis of debt predicts that there is an optimal debt ratio which helps to maximize the value of a firm. Optimal point can be hit when the benefits of debt issuance countervails the increasing present value of costs related to more debt issuance (Myers, 2001). Major benefit of debt is to minimize the interest payments. Such benefits stimulate firms to use debt. Miller (1977) explains this simple effect gets complicated with the existence of personal taxes and sometimes with non-debt tax shields (DeAngelo & Masulis, 1980). Moreover, equity issuance means to move away from optimum therefore this can be considered as a bad news. Myers (1984) further documented that they would opt to issue equity if they feel it is mispriced in market. On the contrary, investors become conscious that the equity issuance is fairly priced or mispriced. Consequently, equity issuance leads investors to react negatively and management doesn't show any interest to issue equity.

### **2.3 Pecking Order Theory**

Pecking order theory, proposed by Myers (1984), explains that firms most likely prefer to finance new investments, first with internally raised funds, i.e. retained earnings, then with debt, and issue equity as a final resort. This theory explains the financial decision making of the firms. According to Shyam-Sunder and Myers (1999), pecking order theory anticipates the impacts of profits correctly. Whereas, according to Fama and French (2002) and Frank and Goyal (2003), the theory has few other complications as well. As currently, it is not that much helpful in managing firms financial resources.

### **2.4 Human Capital Theory**

Adam Smith defined human capital as the skills (intellectual, physical and psychological), and the way an individual adapts to judge about different things (Smith, 1937). It is developed from both the experience and formal schooling (Naslmosavi et al., 2013). Shultz (1961) and Becker (1964) presented the concept of human capital in the mainstream academic research during 1960s. Since then, it has fuelled considerable debate among researchers.

It has been argued by Zingales (2000) that the importance of human capital has emerged as an important asset in the modern technologically oriented economy. It is no longer a reasonable approach to represent a firm by its physical capital. With respect to understanding the modern developments, it is thereby necessary to think about the other resources that help maximizing the value of a firm and how capital structure is managed. A very few studies have tried to investigate the relation between human capital and leverage, i.e. Chammanur et al. (2013) and Akyol and Verwijmeren (2013), who looked into the impact of leverage on human capital/employee wages.

## **3 INDEPENDENT VARIABLES**

### **3.1 Size**

It appears that an agreement is present between theories regarding the positive impact of size over the capital structure of firm even if their explanation varies. From the trade-off theory's viewpoint, corporations trade-off takes place between the leverage benefits for example alleviation of problems of agency or tax savings in opposition to the costs of leverage for example the bankruptcy costs. It is argued by Rajan and Zingales (1995) that the large companies tend to experience bankruptcy less frequently because they have a tendency to be more diversified. Therefore, a practical positive dependence is anticipated between the size of the firm and leverage. On the other hand, due to the information asymmetries, undersized firms have a propensity to experience higher costs to acquire external funds. Furthermore, it is argued by Bevan and Danbolt (2002) that because of the credit rating, larger firms are more prone to encompass the right to use non-bank debt financing. This, in turn, would also advocate a positive association between debt and size.

To measure the size of a firm, natural logarithm of sales will be used in this study, this measure is also consistent with many previous studies (e.g. Rajan and Zingales, 1995; Titman and Wessels, 1988; Hernádi & Ormos, 2012). This measure makes the variations smooth in the figure over the time period.

### **3.2 Tangibility**

Collateralised assets are deemed as an imperative driver that has an influence on the firm's capital structure decision. Tangible assets might be utilized as collateral. Therefore, the risk of the creditor is inversely proportional to the ratio of tangible assets i.e. creditor's risk would be lesser if the fraction of tangible assets is greater, and, consecutively, the value of assets is higher in the case of liquidation and bankruptcy. It is stated by Booth et al. (2001) that 'The more tangible the firm's assets, the greater its ability to issue secured debt and less information revealed about future profits'. Experimental researches that provides support to this association are carried out by Titman and Wessels (1988) and Rajan and Zingales (1995).

We expect positive relation between tangibility (TANG) and leverage (Rajan & Zingales, 1995; Chen et al., 2013). We use fixed assets over total assets (FA/TA) as a proxy to determine firms' tangibility, as computed by Chakraborty (2013).

### **3.3 Profitability**

Since, Modigliani and Miller (1958) much hypothetical work is being carried out, no reliable empirical results have been achieved in this regard until now. Considering the trade-off theory's viewpoint, the level of the profitability of the firm is more if the leverage is higher because of the debt tax deductibility of payment of interest. It is further argued by Rajan and Zingales (1995) that suppliers of debt must be more eager to lend to firms that are profitable.

This study expects negative relation between leverage and profitability, empirical evidence has shown that profitability is negatively related to debt ratios (Bevan & Danbolt, 2002). Profitability can be measured as earnings before interest and tax over total assets (EBIT/TA) as previously measured by Booth et al. (2001) and Shah and Khan (2007).

### **3.4 Growth**

It has been pointed out by Myers (1977) that the companies with higher growth rate will abandon investment opportunities with a positive NPV (net present value) to demonstrate increased corporate value and wealth of shareholders. Hence, growth opportunities have positive effect on corporate value (King & Santor, 2008). A negative relationship is stated between financial leverage and growth by Myers (1984) because of restrictive covenants or high rates of interest that depress debt taking. Such a negative relationship is attributed by Titman and Wessels (1988) because of bondholders' unwillingness to lend to equity-controlled firms like the latter have a tendency to invest sub-optimally to confiscate wealth from bondholders. This study also expects the negative association between growth and capital structure.

To capture firm's growth (GROW), geometric average of five-year sales growth to total asset growth will be applied (Chen, 2004; Delcours, 2007; Hernádi & Ormos, 2012).

### **3.5 Non-debt Tax Shield**

The benefit of tax shields on the utilization of debt finance might either be diminished or even eradicated when an income is reported by a corporation that is constantly low or negative. As a result, the load of payments of interest would be experienced by the firm. It is exhibited by DeAngelo and Masulis (1980) that the alternative of the tax shields on debt financing is non-debt tax shields (NDTS).

Experimental answers are mixed regarding this issue. A strong direct association between the relative amount of NDTS and debt is demonstrated by Bradley et al. (1984). In favour of an effect on debt ratios that results from non-debt tax shields, no support is discovered by

Titman and Wessels (1988). A considerable negative association is reported by Wald (1999) between NDTs and debt. Viviani (2008) has illustrated a considerable inverse association only between NDTs and short-term debt ratio. A negative yet less considerable association is shown by Bauer (2004) between the measures of leverage and non-debt tax shields.

We expect negative correlation between leverage and Non-debt Tax Shield (NDTS) (Hernádi & Ormos, 2012). Following Akhtar and Oliver (2009), we delineate non-debt tax shield as total annual depreciation expense divided by total assets' book value.

### **3.6 Firm Age**

Taking firm's age into account as a probable determinant, like in experiential studies, is not common, while a few connected to debt level can actually be revealed (Johansen & Bartholdy, 2011). It may possibly be squabbled that businesses with relationship of several years with bank are going to experience lesser borrowing costs (Michaelas et al., 1999). It is discovered by Petersen and Rajan (1994) that older companies encompass higher debt ratios as they are required to be higher quality companies.

From the perspective of Pakistan, this is the first study to compute this determinant of capital structure. Not a much literature has been seen on the firm age (AGE), but still according to the few studies, negative relationship is expected (Michaelas et al., 1999). AGE is measured by following Michaelas et al. (1999) and Akhtar and Oliver (2009) as the years from the date of incorporation.

### **3.7 Uniqueness**

The selling expenditures and Research and Development (R&D) are at the starting and the closing stages of the production value chain. Unique goods in fact encompass more selling expenses and R&D, since they are not a replica of formal monotonous things, and as they have particular demands and specific consumers. Similarly, producer of distinctiveness goods is likely to face more risk of bankruptcy; therefore, they have to pay attention towards induced expense of bankruptcy, by means of issuing debt. Because of the constraints in attaining the R&D expense data, this research like the majority of the earlier studies attempts to make use of selling expense, as a substitute for R&D; therefore uniqueness is described by selling expense divided by net revenue from sales. In line with the trade off theory, firms in the midst of unique products encompass lesser debt in their capital structure (Titman & Wessels, 1988). Hence, this study also expects negative relation.

It's hard to find any study in context of Pakistan, which has investigated this determinant with capital structure; this study might be the first to present empirical findings on this association. Empirical findings on uniqueness are still rare. Following Sporleder and Moss (2004), Yang et al. (2010) and Jahanzeb and Bajuri (2014), this study uses selling expense over sales (SE/S).

### **3.8 Risk**

As stated by Bauer (2004), volatility or business risk may be considered as the proxy for firm's risk. Leverage ratio can be less if a firm has less risky position. Therefore, generally, there is a presumption of inverse relation between capital structure and volatility. On the basis of the results presented by Hsia (1981), Huang and Song (2002) state, "As the variance of the value of the firm's assets increases the systematic risk of equity decreases. So the business risk is expected to be positively related to leverage". Huang and Song (2002) and Kim and Sorensen (1986) also confirm this association. However, Titman and Wessels (1988) and Bradley et al. (1984) demonstrated the negative relation.

This study also expects the negative relation between business risk (RISK) and debt (Dang et al., 2012). Standard deviation of return on assets over three years has been used as the proxy to measure business risk (Booth et al., 2001; Hernadi & Ormos, 2012).

### **3.9 Liquidity**

Net effect of liquidity on capital structure is unidentified and it has both the positive and negative impacts (Mouamer, 2011). Firms having high liquidity ratio may have high debt level because of their need to meet debt obligations. This suggests a positive relation between liquidity and capital structure. On the other hand, having more liquid assets, shows that these assets would be utilized as the financing source in future. Hence, this suggests negative relation between liquidity and debt.

This study hypothesizes negative relationship between the liquidity and capital structure (de Jong et al., 2008). To measure liquidity, this study employs the ratio of current assets over current liabilities (Mouamer, 2011).

### **3.10 Human Capital**

Although, the theoretical and empirical literature on the relation between human capital and capital structure is still rare, but there are quite a few recent studies available. The main finding of study presented by Akyol and Verwijmeren (2013) is that there is a positive correlation between leverage and wages paid to the employees, which means companies having higher leverage, must disburse higher wages to their employees. Chemmanur et al. (2013) conclude that a significant and positive association is present between leverage and average employee.

This study investigates the reverse relationship, i.e. impact of human capital on leverage. This kind of relation has not been tested yet, as there is no any evidence available regarding this relation in literature. In this regard, there is only one study available that was conducted by Hovakimian and Li (2011), which failed to determine the relation between employee wages and leverage. This study measures human capital by total salaries and wages of a firm (Jahanzeb et al., 2014).

## **4 METHODOLOGY**

Independent variables and dependent variable have been selected in accordance with the academic literature. Consequently, methodology has been described here to test different hypotheses and analyze those variables empirically. To construct the model, panel data techniques have been used. Panel data consists of both the time-series elements and cross-sectional elements; time-series elements reflect the time period of the study (2004-2013) and cross-sectional elements reflect (200) non-financial companies.

$$LEV_{it} = \beta_0 + \beta_1(SIZE)_{it} + \beta_2(TANG)_{it} + \beta_3(PROF)_{it} + \beta_4(GROW)_{it} + \beta_5(NDTS)_{it} + \beta_6(AGE)_{it} + \beta_7(RISK)_{it} + \beta_8(UNIQ)_{it} + \beta_9(LIQ)_{it} + \beta_{10}(HC) + \varepsilon_{it} \quad (1)$$

(Pooled model)

$$LEV_{it} = \beta_{0i} + \beta_1(SIZE)_{it} + \beta_2(TANG)_{it} + \beta_3(PROF)_{it} + \beta_4(GROW)_{it} + \beta_5(NDTS)_{it} + \beta_6(AGE)_{it} + \beta_7(RISK)_{it} + \beta_8(UNIQ)_{it} + \beta_9(LIQ)_{it} + \beta_{10}(HC) + \varepsilon_{it} + \mu_{it} \quad (2)$$

(Fixed effects model)

In accordance with Drobetz *et al.* (2013), this study follows the model that is presented by Blundell and Bond (1998) for “System GMM Estimation” and applied “xtdpdsys” STATA estimation.

$$\Delta LEV_{it} = (1 - \lambda)\Delta LEV_{i,t-1} + \lambda\beta\Delta X_t + \Delta\varepsilon_{i,t} \quad (3)$$

Where:

*LEV* = leverage ratio of a firm

*SIZE* = size of a firm

*PROF* = profitability of a firm

*GROW* = growth of a firm

*NDTS* = non-debt tax shields of a firm

*AGE* = age of a firm

*RISK* = business risk of a firm

*UNIQ* = uniqueness of a firm

*LIQ* = liquidity of a firm

*HC* = human capital of a firm

$\beta_0$  = common y-intercept

$\beta_1 - \beta_{10}$  = coefficients of the independent variables

$\varepsilon_{it}$  = error term of firm *i* at time *t*

$\mu_{it}$  = fixed effects of firm *i* at time *t*

#### 4.1 Data

Data were collected from Thomson Reuters Datastream. Financial institutions were excluded from the analysis, because of their different financial policies than those of non-financial firms. The data relates to eight non-financial sectors, i.e. automobile & parts, construction & material, chemicals, textiles, food processors, electricity, oil & gas and household goods. We conducted analysis of 200 listed Pakistani (non-financial) companies from the period of 2004 to 2013 (i.e. 10 years).

#### 4.2 Dependent Variable

Capital structure is considered a comprehensive term, which has been measured differently by different authors. However, this study measured capital structure with leverage. Following Lemmon *et al.* (2008) and Mateev *et al.* (2013), this study measures dependent variable by total debt ratio (TD), that is, total debt to total assets.

$$\text{Total Debt (TD)} = \frac{\text{Current Liabilities} + \text{Non-Current Liabilities}}{\text{Total Assets}} \quad (4)$$

## 5 EMPIRICAL RESULTS

Empirical findings have been demonstrated in this section. The table below shows the summary statistics of dependent and independent variables. The total debt ratio demonstrates that the 53.75% firm assets are financed by debt, during this period of study. However, if we compare this ratio with G-7 or other developing countries, it can be argued that firms in Pakistan seem to be more leveraged than those of Jordan, Brazil, Mexico, Malaysia, Zimbabwe and Thailand (Rajan & Zingales, 1995).

Table 2 demonstrates the results of Pearson Coefficient Correlation Matrix. It can be noticed that the size, profitability, non-debt tax shield, uniqueness, liquidity and human capital remained negatively significant and firm age positively significant with the total debt. However, tangibility, growth and business risk remained insignificant.

Table 3 shows the results of different models employed in this study, i.e. pooled OLS, panel, and generalized method of moments (GMM). It shows that the overall results from both the pooled and panel data estimations remained the same, however, a few independent variables remained insignificant in GMM analysis. Further discussions have been presented in the section below.

## 6 DISCUSSION AND CONCLUSION

This study tried to investigate the determinants of capital structure of non-financial Pakistani firms that are listed on Karachi Stock Exchange. The study first time employed the data of 200 listed companies (2000 observations) for the period of 10 years, i.e. 2004-2013, from eight different non-financial sectors, which have not been employed before. Most of the previous studies in this research area have been unable to collect that much data. The study employed pooled, panel, and dynamic panel data estimations.

Tab. 3 – Regression Results. Source: Developed by authors.

According to the empirical findings, liquidity and profitability remained significant and negatively correlated to debt, which supports the hypothesis of pecking order. Firm size

\*\*,\* indicate significant levels at 1% and 5% respectively. Models are corrected for heteroscedasticity. Probability levels are shown in parentheses. Debt(-1) is the first lagged dependent variable. Significance of lagrange multiplier test shows the acceptance of panel data estimation over pooled analysis. However, fixed effects should be used because of the significance of Hausman Test, which shows the applicability of fixed effects over random effects. Sargan overidentifying restrictions are valid. If p-value > 0.05, we confirm the null hypothesis that the overidentifying restrictions are valid. It reveals the acceptance of model.

remained significant and positively correlated with debt, which supports the idea that the larger firms are less likely to bankrupt, hence, may easily acquire external debt financing. Firm age showed positive and significant relation with capital structure, which shows that the older firms are capable to raise their external debt financing. Growth remained significant in all models. More importantly, human capital remained negative with debt ratio in all the different models. This shows that the companies which spend more on their employees tend to decrease their debt levels to save their cost of capital, and they might have access to utilize retained earnings or other internal debt financing. Further studies may be conducted by categorizing the data into sectors, which will assist the investors and managers to apprehend the complications related to any particular sector, because every sector might behave differently towards capital structure.

## **EVALUATION OF INVESTMENT STRATEGIES CREATED BY MULTIOBJECTIVE GENETIC PROGRAMMING**

*Martin Jakubáci*

### **Abstract**

Genetic programming became very popular in the last years, because it offers an automated way of creating tree like solutions to many problems, also in the area of financial investing. Although there are many publications about these applications, proper evaluation is mostly missing. The solutions are mostly compared only to the most basic buy and hold strategy. We propose a set of strategies that can be used to evaluate the rules created by genetic programming. Our implementation of multiobjective genetic programming is creating stock evaluation rules based on historical prices and internet term popularity and these rules are used in investment strategies for stock portfolio creation. Goal is to compare the returns and risk of this implementation with the proposed strategies. It is shown, that our implementation outperforms the other strategies in most of the cases.

*Keywords: genetic programming, investment strategy, stock portfolio*

JEL Classification: G11

## **1 INTRODUCTION**

Financial markets are complex systems, which are hard to predict. Investors create portfolios of assets to achieve high profit and minimize the risk. Low prices of hardware and data availability caused high interest in computer modelling in the area of investing. Popular group of algorithms, that are used for modelling are the evolutionary algorithms. One of them is genetic programming, which uses operators inspired by the evolution theory to generate tree programs. These programs can represent also stock evaluation rules, which can be used in investment strategies to create portfolios. Most of the research in this area compares the results only with the most simple buy and hold strategy, although wider evaluation should be done.

## **2 INVESTMENT STRATEGIES**

There are multiple models and strategies. Efficient market hypothesis believes, that financial markets are effective and every information is immediately absorbed. The price of the asset reflects all information and is equal to the real value (Beechey, Gruen & Vickery, 2000, p. 2). Changes in price are random fluctuations around this value and can be described as a random walk (Alexander, 2008, p. 134).

When investing, there is always some risk. Modern investment strategies are based on diversification, investing in multiple assets (Bohdalová & Greguš, 2011, p. 2). This was formalized by Harry Markowitz as multiobjective problem, where the objectives are revenue maximization and risk minimization. Investment strategy is a rule, which specifies investor's position on every asset in time  $t$ . The position is chosen based on the available information, without the knowledge of the future (Bohdalová & Greguš, 2012, p. 21). When optimizing this multiobjective problem, there is no single best solution. Multiple optimal solutions are found, which are called Pareto optimal and form the Pareto front. Value of none of the

objectives of these solutions can be increased without sacrificing value of a different objective (Hassan, 2010, p. 10).

Investors opposing the efficient market hypothesis believe, that the market can be outperformed and high returns can be achieved. Many strategies are based on the fundamental analysis. Its main idea is that real value of a stock and its price on the market can differ and it should be invested into undervalued companies. Finding the real value is not an easy task, it requires analysis of financial and other data (Thomsett, 2006, p. 2).

Other group of strategies is based on the technical analysis. The future prices are predicted from the historical prices. It is based on three principles. The first one is that the price reflects everything, the second one is that prices move in trends and the last one is that history repeats (Chovancová, 2006, p. 315). The strategies are based on the study of charts or technical indicators, for example moving averages, which are used to smooth the time series by averaging the data from previous points (Chovancová, 2006, p. 327-328).

In the recent years research is done also in the area of forecasting based on Internet activity data. Big interest was caused by the article dealing with market index changes correlated with Google Trends changes of different terms (Preis, Moat & Stanley, 2013). Similar research was done also with:

- Page views on Wikipedia (Moat et al., 2013).
- Terms in Facebook statuses (Karabulut, 2013).
- Twitter posts (Ruiz, Hristidis, Castillo, Gionis, & Jaimes, 2012).

### **3 GENETIC PROGRAMMING**

Genetic programming is an evolutionary optimization algorithm, which is searching for problem solutions. Solution is a program represented by a tree structure. First generation of solutions is created randomly. Every next generation is created by stochastic transformation of the previous generation. Transformation is done by applying operators, which are inspired by the evolution theory. These operators are mostly selection, mutation and crossover. Every next generation is expected to be better, the quality of the solutions is evaluated by the fitness function (Poli, Langdon, & McPhee, 2008, p. 2).

The most frequently used representation of a solution is a syntactic tree. The solution is in fact a program, which can be split into commands, organized as a tree. Programs can be represented also in the prefix form, which is known from the functional programming.  $max(x+x, x+3*y)$  is written as  $(max (+ x x) (+ x (* 3 y)))$ . The relation between commands and subcommands is more obvious in the prefix form.

The tree based solutions are formed from 2 different sets of vertices. The first group are terminal symbols, for example inputs, constants or any method calls, which do not accept any parameters. Those are leafs of the tree structure. The second set are nonterminals, or functions, that accept parameters. For example arithmetic operators, logical operators, conditions etc. They are expected to be type and run safe, so that the solutions can be executed to transform inputs to outputs. The first vertex in the tree is called root and the depth of every vertex is defined as the distance from the root.

First step during the run of the genetic programming is the initialization of the population (the set of the solutions). This done by creating random solutions. Two common methods are the full method, where every leaf has the same depth, equal to the maximum depth specified for the solutions. The other method is the rising method, where terminals and nonterminals are

applied randomly and the depths are different, but never more than the maximum depth. Maximum depth is important to avoid very large trees, which are too time consuming.

The other generations are created by applying genetic operators. Part of the new generation is created by copying best solutions from the previous generation. The other operator is the mutation, where a random subtree or leaf is replaced by a random subtree or leaf. Crossover is similar, but two solutions exchange their random subtrees or leaves (Poli et al., 2008, p. 9-27).

As already mentioned, the quality of the solution is evaluated by the fitness function. Solution is filled with inputs, executed and the output is evaluated. When dealing with multiobjective optimization, there are multiple fitness functions required, one for every objective. There are many algorithms to handle multiple objectives in evolutionary algorithms, overview can be found in (Ghosh & Dehuri, 2005). SPEA2 was chosen, because it overcomes some issues in other algorithms. It's based on elitism, Pareto dominant solutions are kept in a separate archive with fixed size (Hassan, 2010, p.20). The algorithm works this way (Zitzler, Laumanns, & Thiele, 2001, p. 5):

1. Initialization - Generate an initial population and create the empty archive (external set). Set  $t = 0$ .
2. Fitness assignment - Calculate fitness values of individuals in population and archive.
3. Environmental selection - Copy all nondominated individuals in population and archive to the new archive. If size of the new archive exceeds  $M$  then reduce new archive by means of the truncation operator, otherwise if size of new archive is less than  $N$  then fill new archive with dominated individuals in population and archive.
4. Termination: If  $t \geq T$  or another stopping criterion is satisfied then set  $A$  to the set of decision vectors represented by the nondominated individuals in the archive. Stop.
5. Mating selection: Perform binary tournament selection with replacement on the new archive in order to fill the mating pool.
6. Variation: Apply recombination and mutation operators to the mating pool and set new population to the resulting population. Increment generation counter ( $t = t + 1$ ) and go to Step 2.

#### **4 RELATED RESEARCH**

Muller & Beling (1998) used genetic algorithm to find the weights of a linear combination evaluating stock, with 9 objectives. They compared the results with a polynomial network without definitive conclusion. Becker, Fei & Lester (2007) were able to outperform the market with their genetic programming solutions for picking stocks from S&P300 index with 3 objectives. Huang, Chang, Chang & Cheng (2011) outperformed the market with their single objective genetic algorithm, which was used to tune the parameters of their fuzzy model. Then they improved the results by implementing a twoobjective NSGA II algorithm (Chen, Huang & Hong, 2013) and adding domain knowledge (Chen, Huang & Hong, 2014).

Another area of research deals with generating trading rules. These are tree structures, which return a logical value, which decides whether to enter or leave the market. Allen & Karjalainen (1999) were first to experiment on S&P 500 index, but failed to beat the market. Neely (1999) and other researchers added risk as a second objective, but still failed to beat the market. Potvin, Soriano & Vallée (2004) were only able to beat a stable or falling market. Becker & Seshadri (2003) made some modifications to the typical approach and beat the

market. They used monthly data instead of daily, reduced the number of functions, increased the number of precalculated indicators (so in fact increasing domain knowledge), coevolved separate rules for selling and buying, penalized more complex solutions and took into account the number of profitable periods instead of the total revenue. Lohpetch & Corne (2009, 2010) were analyzing the differences between the different approaches and found out, that longer trading periods (monthly instead of daily) and introduction of a validation period are causing better results. Their NSGA II implementation was able to beat the singleobjective solution and also market and US bonds (Lohpetch & Corne, 2011). Briza & Naval (2008) used the multiobjective particle swarm algorithm with revenue and Sharpe ratio as objectives and outperformed market and 5 indicators (moving averages, moving average convergence - divergence, linear regression, parabolic stop and reverse and directional movement index) on training period, but failed to outperform market on testing period.

A lot of research was done in the typical problem of portfolio optimization, where the optimal weights of stocks in a portfolio are searched. Many single and multiobjective evolutionary algorithms were used and compared, an overview was done for example by Tapia & Coello (2007) and Hassan (2010).

Chen & Navet (2007) criticize the research in the area of genetic programming usage in investment strategies and suggest more pretesting. They compare strategies with random strategies and lottery training without getting good results. Genetic programming should prove its purpose by performing better than these random strategies, according to them.

## **5 GOAL**

Our goal is to evaluate our implementation of genetic programming by comparing its result with a set of investment strategies. To prove its usability, it should outperform most of the strategies in the experiments. Our hypothesis is that our algorithm will have the highest rate of return in most of the cases.

## **6 METHODS**

Our implementation of genetic programming is compared with a set of investment strategies. To compare them, we run an investment simulation and calculate:

- Rate of return (RoR)  $r = \frac{R_t - R_0}{R_0}$ , where  $R_0$  is the initial value and  $R_t$  is the final value, after.
- Standard deviation of returns  $\sigma_i = \sqrt{\frac{1}{T} (\sum_{i=1}^T (r_i - \mu)^2)}$ , where T is the number of periods,  $r_i$  is the return rate at time i and  $\mu$  is the average rate of return.

### **6.1 Implementation**

Genetic programming is used to generate stock evaluation rules using internet popularity data from Google and Wikipedia (of the company names as terms), together with historical prices, as described in (Jakubeci, 2014). The rule is then used for daily investing in the 30 Dow Jones Industrial Index companies. Used fitness methods are rate of return and standard deviation of returns. These functions were used:

- arithmetic operations: addition, subtraction, multiplication, division, negation and exponentiation,
- logical operations: conjunction, disjunction, negation,

- equality: higher, lower, equal, or any combination,
- trigonometric operations: sine, cosine,
- condition,
- list operations: lag, moving average.

Implementation was done in the C# language, which has a high performance but is still easy to use. The language integrated many features from dynamic programming, for example the expression trees, which allow working with an algorithm as a data structure. This is important for the genetic programming algorithm, because it allows modifications in the solutions and application of the evolutionary operators. The Metaling library was used, to simplify these modifications (at <http://metaling.codeplex.com/>).

## **6.2 Compared strategies**

Strategies created by the genetic programming implementation were compared with a number of strategies:

- Lottery trading is doing decisions randomly. That means, that it always gives a random evaluation of a stock.
- Random strategy is a randomly created strategy. Such strategies are created also in the first generation of the genetic programming simulation.
- Risk free investment is represented by 3 year US treasury bonds.
- Buy and hold strategy means that the asset is bought on the beginning of the period and sold at the end. It is the most basic strategy and it was applied to the DJI index.
- Dogs of the Dow strategy is investing to 10 companies from the DJI index with the highest dividend yield (Domiana, Loutonb & Mossman, 1998, p. 1).
- Simple moving averages (SMA) is calculated as an average of previous days, when the price rises above the moving average, stock should be bought, when it falls under the moving average, it should be bought (Kirkpatrick & Dahlquist, 2010, p. 280-281).
- Exponential moving averages (EMA) is similar to the SMA, but with decreasing effect of the older days in the calculation (Kirkpatrick & Dahlquist, 2010, p. 282).
- Moving average convergence divergence (MACD) is calculated as a difference between 26-period EMA and 12-period EMA, when it crosses the signal line (EMA of MACD) from below, it is a buy signal (Kirkpatrick & Dahlquist, 2010, p. 432-433).

## **6.3 Data**

Rules from genetic programming are trained on data of DJI companies from years 2010-2013 and evaluated on data from year 2014. We used different data sources:

- historical prices were downloaded from Yahoo Finance, at <http://finance.yahoo.com/>
- Google term popularity was downloaded from Google Trends service, at <http://www.google.com/trends/>
- Wikipedia article popularity was downloaded from Wikipedia article traffic statistics, at <http://stats.grok.se/>

## 7 RESULTS

We present the results of training and evaluation runs. The results representing the genetic programming implementation are from the averages of Pareto front from 20 runs. Lottery trading is called Random or Rnd, random strategy is called RandomTree or RndTree in the charts and tables, buy and hold is called DJI and Dogs of the Dow is DOG. We present the results separately for the training period and evaluation period.

### 7.1 Training

Distribution of the rules created by genetic programming can be seen on fig. 1, yearly average rate of return is on the y axis and standard deviation on the x axis. The Pareto front can be seen in the upper left area. This is the result of one simulation run on the training period of 2010-2013. Separate comparisons without transaction costs and with transaction costs of 0,5% were done.

Fig. 1 – Results of return and risk distribution of the rules created by genetic programming in one of the training runs.

Fig. 2 – Portfolio value results of the strategies on the training data set, without trans. costs.

Tab. 1 – Results of the strategies on the training data set, without transaction costs.

	DJI	DOG	Bonds	GP	Rnd	RndTree	ma10	ema	macd
RoR	0,458	0,788	0,018	0,824	0,446	0,296	0,573	0,587	0,619
StdDev	0,128	0,187	0,004	0,174	0,104	0,086	0,150	0,134	0,128

Fig. 3 – Portfolio value results of the strategies on the training data set, with 0,5% transaction costs.

Tab. 2 – Results of the strategies on the training data set, with 0,5% transaction costs.

	DJI	DOG	Bonds	GP	RndTree	ma10	ema	macd
RoR	0,458	0,788	0,018	0,692	0,267	0,568	0,582	0,614
StdDev	0,128	0,187	0,004	0,157	0,083	0,150	0,135	0,128

Genetic programming outperformed all strategies, when transaction costs were ignored. With 0,5% transaction costs, it was outperformed only slightly by Dogs of the Dow. Standard deviation was lower for genetic programming than for Dogs of the Dow in both cases. Performance can be seen on fig. 2 and 3 and in tab. 1 and 2. Lottery trading was removed because of very poor results with transaction costs.

## 7.2 Evaluation

Evaluation was done on the data from the first half of 2014. Separate comparisons without transaction costs and with transaction costs of 0,5% were done.

Fig. 4 – Portfolio value results of the strategies on the training data set, without transaction costs.

Tab. 3 – Results of the strategies on the evaluation data set, without transaction costs.

	DJI	DOG	Bonds	GP	Rnd	RndTree	ma10	ema	macd
RoR	0,046	0,063	0,022	0,097	0,049	0,060	0,001	0,002	0,026
StdDev	0,031	0,03	0,001	0,029	0,018	0,019	0,015	0,018	0,019

Fig. 5 – Portfolio value results of the strategies on the evaluation data, with 0,5% transaction costs.

Tab. 4 – Results of the strategies on the evaluation data set, with 0,5% transaction costs.

	DJI	DOG	Bonds	GP	Rnd	RndTree	ma10	ema	macd
RoR	0,046	0,062	0,021	0,070	-0,134	0,055	-0,005	-0,003	0,021
StdDev	0,031	0,029	0,001	0,024	0,042	0,018	0,015	0,017	0,019

Strategies created by genetic programming were able to outperform all strategies, even with transaction costs. Performance can be seen on fig. 4 and 5 and in tab. 3 and 4.

Genetic programming strategies give the best results, but buy and hold strategy used on market indexes is quite strong as well. Random solutions are hurt by the transaction costs. Lowest level of standard deviation is held by bonds, but that is logical, it has also very low rate of return. Strategies based technical analysis keep low levels of standard deviation but are hurt probably by the short period of evaluation.

## 8 CONCLUSION

The performance of rules created by genetic programming was compared to different strategies, consisting of random approaches, bonds, buy and hold and some well-known strategies. They compete very well and were outperformed only by the Dogs of Dow on the training set with transaction costs. Our implementation has the highest rate of return in most of the cases, so our hypothesis was confirmed.

We think that such evaluation proves the usability of our implementation and that similar evaluation should be done with all similar approaches in the area of financial investing. Outperforming only buy and hold strategy on one period is not enough to prove usability.

Experiments were done only in the period of 2010-2014, which was a typical rising period. Interesting experiments could be done also on different types of periods, for example before and during the financial crisis. This was a typical falling period and it would be interesting to see the results. It would be also interesting to compare different combinations of training and evaluation periods, for example training before the crisis and evaluation during crisis.

The experiments could be in future enhanced also with other strategies and longer periods.

## **PHILANTHROPY IN TERMS OF TAX POLICY IN THE CZECH REPUBLIC**

*Jana Janoušková*

### **Abstract**

Funding non-profit sector is a current issue in the Czech Republic, because the non-profit sector plays an irreplaceable role in the economy. It fulfills a number of tasks in the areas of public interest such as social, cultural, environmental, educational, sports, etc., where the main goal is not to make a profit, but the public benefit. The aim of the paper is to show support for philanthropy with the help of government fiscal instruments and explain the process of how these options are used by taxpayers.

*Keywords: non-profit sector, tax policy, income tax, donation, tax deductions*

JEL Classification: E62, H2, M1

### **1 INTRODUCTION**

The aim of the non-profit sector is to consolidate its position in a society. Nonetheless, raising funds to meet the goals and objectives is not easy. Possibilities of obtaining funds from their own activities are limited in non-profit organizations (membership fees, admission, advertising, etc.). Therefore, external resources represent a principal source of funding, particularly in the form of subsidies whether they are obtained from the government or within various EU programs. Subsidies represent a substantial part of all resources for a large number of NGOs.

Another possible source of funding besides subsidies is a donation while the form of legislative support varies in individual countries. The promotion of donation is realized in the form of tax relief in most countries (European Commission, 2014). Basically, there are three types of preferential schemes (Klik, 2001):

- Item reducing the tax base (tax deduction), when the value of donation is deducted as a tax deductible item from the tax base (this form is used in the Czech tax law).
- Item reducing the tax payment (tax credit), when a taxpayer has the opportunity to decide on the levy of taxes in favour of non-profit sector. However, they have no possibility to determine the beneficiary directly, i.e. a specific recipient of a gift. This is the main difference compared to tax assignment (but this form does not occur in European countries).
- Tax assignment (tax rebate) this is a possibility to remit a part of tax liability to a directly appointed subject without additional costs (e.g. it is used in tax systems in Slovakia, Hungary, Poland, Lithuania, Portugal).

Support of the non-profit sector, provided in the form of tax relief, depends not only on a form of tax relief but also on the method of income taxation (Příbyl, 2006), respectively on a model of personal income tax. Tax relief should have a lower impact on a taxpayer, a donor, in the system with a linear tax rate than in the case of a progressive tax rate.

The nature of tax incentives should lie in the rate of proportionality between the taxpayer and the extent to which they will transfer the tax burden to the state using tax savings. Stimulation

is relatively strong in case of tax assignment. This is because the taxpayer has the opportunity to provide support without any strain on their donation. Particularly, it depends mainly on their willingness to support a given non-profit organization and to take required steps for that purpose. The general attitude of the society towards the non-profit sector plays an important role.

## **2 FISCAL INSTRUMENTS IN THE CZECH TAX LAW**

There is the support of donation in the form of itemized deduction from the tax base in the Czech tax legislation for many years. A minimum deductible amount is established as well as a maximum one, both for physical and legal persons (Trezziová, 2006). In practice, it is necessary to be careful and do not confuse donations with sponsoring, or providing promotional or advertising services through non-profit organizations. A donor, unlike a sponsor, lets a non-profit organization know that they support the organization's activities, regardless of other possible advantages for the company.

The gift is newly understood as a “gratuitous performance” in the context of recodification of civil law, starting in 2014. In terms of income, donations are categorized into gratuitous income.

Hence, the gift can be perceived as gratuitous performance given to selected non-profit organizations (respectively individuals), which is based on a donation contract. Owing to taxation relief, it is necessary to state the purpose of the dedicated gift. A claim to tax credits arises if the purpose is in accordance with the Income Tax Act. Donors are divided from this point of view into two basic groups:

- Individual (physical person) - which may be an ordinary citizen, an employee, or a person who has income from independent activities or lease, or from other activities.
- Legal entity - business entity.

The tax regime with the possibility to deduct donations and thus reduce the tax base is different for the above-mentioned groups (Act No.586/1992 Coll. on Income Tax as amended). According to the Income Tax Act, a donor - physical person may deduct the value of a gift from their tax base if the total value of donations in a given year is greater than 2 % of their tax base, or is at least CZK 1,000. However, it is possible to deduct the maximum of 15 % of the tax base. At the end of 2013 there was the maximum limit of 10 % of the tax base.

Tax regime for legal entities is somewhat different. A donor - legal entity is entitled to deductibility if the value of one gift (or all gifts of one organization) is at least CZK 2,000. In the case of a donation, the donor may apply a deductible item decreasing the adjusted tax base. In contrast to the individual, legal entity reduces the tax base of the item deductible from the tax base (§ 34 of the ITA) as a tax loss deduction, support of research and development, or deduction for vocational training. The value of the gifts can be applied if they conform to the rules laid down by law. If the donor is subject to VAT and gives a gift, it is necessary to pay VAT based on the value of the gift. Financial donations are not subject to the value added tax. For a donor, the VAT is a further cost associated with the gift. Even with legal entities, there is an increase since 2014 and the limit for deduction of donations to the maximum of 10 % of the tax base is unified at the same time.

The gratuitous income of beneficiaries, i.e. public-benefit taxpayers (the definition of which is amended for the purposes of the Income Tax Act) is tax exempt if it is used for the given purposes or as a capital contribution for the taxpayer.

### **3 OBJECTIVES AND METHODOLOGY**

The paper deals with the issue of donations in the context of legislative support for tax reliefs. It points out promoting philanthropy through the fiscal policy of the government and using the options by taxpayers.

The problem is associated with the abolition of tax progression and introduction of the single tax rate of 15 % when the effect of deductibles, mostly used by middle classes, was lessened (Janoušková, 2012). It is also associated with economic recession, when companies seek to reduce costs and willingness to corporate philanthropy is dropping. However, we cannot forget the fact that socially oriented non-profit organizations, which offer the aid to citizens experiencing negative effects of the crisis, are growing in importance in difficult economic situations.

The paper is based on the analysis and subsequent evaluation of secondary statistical data of the Tax Office in the Czech Republic. It is supported by aggregate data derived from filed tax returns (hereinafter referred to as TR) for the period 2000 - 2013. Nonetheless, mathematical calculations have limited explanatory power because many taxpayers, particularly employees, do not file tax returns. They apply tax deductions within the annual settlement of advances of their employers. Alternatively, the taxpayer may be at a loss, or the value of the gift does not meet the above limits and therefore it cannot be claimed as a tax-deductible item. The subject of this research is rather corporate donations that are divided into physical and legal persons.

Furthermore, the paper is based on the results of a primary research focused on corporate philanthropy. The research was carried out in the Moravian-Silesian region of the Czech Republic within the project TA CR in August 2014 with the help of a questionnaire survey. 300 subjects represented the sample size. Calculations were performed according to data of the Czech Statistical Office to 31 December 2012 according to organizational statistics of entities in the Moravian-Silesian region. Only entities with at least one employee were included into calculating quotas. There are 26,718 such entities in the region. The survey results in relation to donations, which are linked to applied fiscal instruments in the Czech Republic, are published in this paper.

### **4 OVERVIEW ON DONATIONS OF INDIVIDUALS AND LEGAL ENTITIES**

Taxes in the society do not function only as a tool of fiscal policy, but they reflect a range of social goals. The purpose of majority of deductibles, contained in the Income Tax Act, cannot be justified by solvency or vertical equity. The aim is to support public policies such as promotion of science and research, promoting old age security, and also supporting philanthropy.

The following calculations indicate a trend in donations in the years 2000 - 2013 in relation to data that can be analyzed and then summarize from TR divided into individuals and legal entities. Calculations are based on countrywide data in relation to data in the Moravian-Silesian region.

#### **Individuals' donations**

There is a growing trend of increasing the total amount of stated donations which can be seen in Table 1 below. In comparison with the year 2000, the total value of donations increased by 127.4 % in 2013. Individuals claimed donations worth CZK 1.5 billion within the tax deduction (the total value of donations amounted to CZK 0.7 billion in 2000). The total value of gifts already remains at CZK 1.4 – 1.5 billion since 2007.

Although the total value of donations in the observed period increases, the average donation per one taxpayer has not such a clear trend. The increase of the value of gifts is accompanied by an increase in the number of taxpayers filing tax returns. The number of taxpayers, claiming a tax deduction for gifts, has increased by 94.4 % in 2013 in comparison with the year 2000. Yet nowadays, the average value of a gift is ranging between CZK 11.000 and 13.000.

Tab. 1 – Development of donations for individuals according to tax returns between the years 2000 – 2013 in the Czech Republic (CR). Source: Tax Office CR, own calculations

Period	Number of individuals TR filed in the CR			Σ Value of gifts (in CZK)	Average value of gifts per 1 TR (in CZK)
	Number TR Σ	TR with gifts	%		
<b>2000</b>	1 448 084	71 494	4,9	669 873 274	9370
<b>2001</b>	1 535 281	78 188	5,1	759 839 513	9718
<b>2002</b>	1 592 244	102 811	6,5	994 675 138	9675
<b>2003</b>	1 598 164	89 275	5,6	911 562 640	10211
<b>2004</b>	1 524 649	92 886	6,1	981 806 435	10570
<b>2005</b>	2 036 101	121 477	6,0	1 192 078 432	9813
<b>2006</b>	2 246 839	132 470	5,9	1 341 090 197	10124
<b>2007</b>	2 348 299	141 093	5,8	1 469 092 117	10412
<b>2008</b>	1 739 241	110 614	6,4	1 425 191 599	12884
<b>2009</b>	1 794 573	113 928	6,3	1 493 532 379	13109
<b>2010</b>	1 834 136	116 959	6,4	1 510 644 604	12916
<b>2011</b>	1 901 065	121 216	6,4	1 466 341 688	12097
<b>2012</b>	1 913 452	124 096	6,5	1 562 469 708	12591
<b>2013</b>	1 937 120	138 966	7,2	1 523 212 081	10961

It is necessary to note that the increase in the number of tax returns between the years 2005 – 2007 is not associated with the emergence of new businesses but with potential application of so called taxation of married couples. For this reason, the data are not used in a comparison in Graph 1. Moreover, there was an increase in the value of gifts in 2002, especially in the context of the devastating flood.

The negative aspect in the development can be probably considered little tax incentives in connection with donations. The average number of taxpayers, claiming a tax deduction for gifts, has not increased and it is around 6.5 %. The following chart shows how many taxpayers - individuals have used the possibility of tax deduction compared with the total number of taxpayers who filed a tax return.

Fig. 1 – Number of taxpayers who use the option of applying donations compared to the total number of tax returns in the Czech Republic - physical persons (in thousands). Source: own calculations.

### Legal entities

Trends in corporate philanthropy are shown in the following table. It is possible to observe that there were 184 million less tax deductibles on donations than the previous year. It can be attributed to the recession of the Czech economy in previous years when companies were searching for cost savings in particular. Yet, compared to the year 2000, almost more than CZK 1.7 billion were applied within adjusted tax basis on donations in 2013. The value of donations has been increased by 224 %. The average value of donations per one entity amounted to CZK 138 thousand in 2013. It represents an increase of almost 74 % since 2000. For individuals, the average value of the gifts did not increased significantly for the given period.

Tab. 2 – Development of donations for legal entities according to tax returns between the years 2000 – 2013. Source: Tax Office CR, own calculations

Period	Number of legal entities TR filed in the CR			Σ Value of gifts (in CZK)	Average value of gifts per 1 TR (in CZK)
	Number TR Σ	TR with gifts	%		
<b>2000</b>	223 307	9 418	4,2	746 389 302	79251
<b>2001</b>	242 164	10 614	4,4	1 017 522 284	95866
<b>2002</b>	265 813	13 845	5,2	1 950 402 720	140874
<b>2003</b>	270 968	12 220	4,5	1 545 325 983	126459
<b>2004</b>	279 964	13 940	5,0	2 068 487 263	148385
<b>2005</b>	296 271	15 839	5,3	2 158 619 224	136285
<b>2006</b>	307 986	16 804	5,5	2 508 014 912	149251
<b>2007</b>	329 481	18 815	5,7	2 508 883 799	133345
<b>2008</b>	347 457	19 223	5,5	2 415 230 148	125643
<b>2009</b>	370 709	17 094	4,6	2 383 775 172	139451
<b>2010</b>	359 084	17 578	4,9	2 460 657 776	139985
<b>2011</b>	365 488	17 765	4,9	2 644 566 577	148864
<b>2012</b>	383 776	17 571	4,6	2 601 867 155	148077
<b>2013</b>	350 370	17 505	5,0	2 417 654 501	138112

The number of entities applying a tax deduction on donations in their tax returns increased by 85.9 % in 2013 compared to 2000. However, as in the case of individuals, less favourable phenomenon is the fact that tax incentives are not sufficient in the context of donations. The number of taxpayers with applied gifts has not increased in comparison with the total number of filed tax returns since 2000. It is about 5 % and the number is even lower compared to donors-individuals.

Fig. 2 – Number of taxpayers (DS) who use the option of applying donations compared to the total number of tax returns in the Czech Republic – legal entities. Source: own calculations.

## **5 DONATIONS DEVELOPMENT IN THE MORAVIAN-SILESIAN REGION**

There has been a substantial change in the industry structure in the Moravian-Silesian region (hereinafter MSR) in recent years. The region belongs to the areas with a low level of employment and deals with problems of creating conditions for new investors. As for developments of filed TR, where the non-taxable portion of the tax base has been applied in the form of donations within the Moravian-Silesian region in comparison to the total TR filed for the whole Czech Republic, the average number of donors is stable in percentage terms over the period concerned, both with individuals and legal entities. It ranges between 9 – 10 % with individuals. Even here it is possible to record an increase in filed TR in connection with taxation of married couples. As for legal entities, it can also be observed that the development of filed TR is stable at around 10 % due to the countrywide number of TR with applied gifts.

Tab. 3 – Development of donations for individuals according to tax returns between the years 2000 – 2013 in the Moravian-Silesian region. Source: Tax Office CR, own calculations

Period	Individuals		Legal entities	
	TR with applied gifts in the MSR compared to TR with applied gifts in the CR (in %)	Average value of gifts per 1 TR (in CZK)	TR with applied gifts in the MSR compared to TR with applied gifts in the CR (in %)	Average value of gifts per 1 TR (in CZK)
<b>2000</b>	9,1	10461	8,8	64352
<b>2001</b>	9,2	10778	9,8	75818
<b>2002</b>	8,9	11189	8,7	90564
<b>2003</b>	9,5	11895	10,1	109197
<b>2004</b>	9,3	12285	9,7	110552
<b>2005</b>	11,4	10512	9,8	171244
<b>2006</b>	11,7	10862	10,3	216331
<b>2007</b>	11,8	10885	10,7	166695
<b>2008</b>	10,1	13158	10,6	162150
<b>2009</b>	9,8	13120	10,2	120157
<b>2010</b>	9,8	13812	10,2	61735
<b>2011</b>	9,7	13830	10,1	55149
<b>2012</b>	9,6	14688	10,2	53546
<b>2013</b>	9,5	12696	9,9	48067

If we take into account the average value of donations per one taxpayer (individual), the Moravian-Silesian region participates in donating significantly and is first in comparison with other regions. And this is despite its problems associated with restructuring. The region was only surpassed by the Plzen and Central Bohemian regions between the years 2010 – 2012 (see Fig. 3).

Fig. 3 – Development of donations with individuals according to tax returns between the years 2000 - 2013 in individual regions in CR (average value of the donation per one TR with applied gifts). Source: own calculations.

A similar trend can be seen also in the development between the years 2000 - 2013 with donors - legal entities. If we compare the average value of a gift per one legal entity - a donor, then the Moravian-Silesian region occupies top positions (see Fig. 4).

Fig. 4 – Development of donations with legal entities according to tax returns between the years 2000 - 2013 in individual regions in CR (average value of the donation per one TR with applied gifts). Source: own calculations.

As it was already mentioned in connection with negative economic developments, a decline of donating may be expected. Nonetheless, the change can be recorded only with legal entities. The average value of the donation per one donor filing a tax return was sharply reduced in the Moravian-Silesian region from 2010 and it is even lower than in 2000.

This phenomenon does not occur with donations of individuals and the average value of the donation is approximately EUR 13 thousand since 2008. The average value of applied donations per individual (physical person) is even higher than the national average.

Primary research (Scientific research "Philanthropy Moravian-Silesian Region companies", 2014) also confirmed the evolutionary trend based on aggregate data from filed TR in the whole Czech Republic. Analysis results show that the annual value of the aid and the specific amount of contributions is determined by companies and mostly they are based on negotiations of a decision-making body in an organization (44.1 %). Subsequently, it is determined according to the profit achieved (30.0 %) and with more than one-sixth of companies it is a subjectively determined constant amount (17.9 %). Tax deductible donation (7.7 %) and other strategies (e.g. collections) amounting to just 6.3 % in the surveyed companies is the least decisive factor. Respondents could give multiple answers. Therefore, the totals do not give 100 %. Results are shown in the following chart.

Fig. 5 – Determination of the annual amount for the support and the specific amount of a contribution. Source: Scientific research "Philanthropy Moravian-Silesian Region companies"

The measure of importance of individual factors for corporate strategy was identified with the use of loads of items. Respondents rated individual factors on a scale from 1 to 4. Tax factors are less important for corporate strategy according to the surveyed companies. Detailed results are presented in the following Fig. 6.

Fig. 6 – Measure of the importance of the given factors for corporate strategy. Source: Scientific research "Philanthropy Moravian-Silesian Region companies"

Several possible solutions were identified within the open-ended questions (without offered options of answers) regarding the aid to corporate philanthropy either at the regional level or at the state level. The most commonly surveyed companies have indicated examples that could be helpful, such as raising of public awareness, better promotion and greater awareness (27.4 %), tax benefits, increasing the tax deduction limit for donations, sophisticated policy of tax credits (26.0 %).

## 6 CONCLUSION

The aim of this paper was to highlight the tax policy of the state, which is intended to encourage philanthropy. In addition to their description, it was explained how the options are used by taxpayers. Most EU countries motivate taxpayers to fund the non-profit sector and employ various tax preferential approaches. These approaches may consist in several facts such as deductible donation amount, the amount of a required minimum donation, or the form of deduction either from the tax base, or tax credit. The countries introduce the possibility of tax assignments and strive for longevity and sustainability of both corporate and individual altruistic behavior.

An approach to the use of fiscal instruments has been stable in the Czech Republic for many years. The support is realized by deducting the value of the donation from the tax base. Progressive taxation of personal incomes was ended in 2008. The abolition of tax progression and introduction of a single tax rate of 15 % has reduced the effect of deductible items used predominantly by middle classes. Initial concerns that the legislative change will reflect in a decline in donations by individuals have not been fulfilled as illustrated by the analysis in the paper. Follows from the above, the trend in growing willingness to donate is rather obvious, despite the adverse economic situation, which affected the Czech Republic in previous years. Steps were taken to increase support for community activities in 2014. The maximum limit of the amount of donations deductible from the tax base for legal entities and individuals was increased.

Corporate philanthropy, especially at small and medium-sized companies, depends on the stability of the economy. Furthermore, the economic downturn exerts the pressure on reducing all costs of companies. Particularly, decline in the average value of donations per one legal entity is noticeable almost in all regions compared since 2009.

The number of donors does not increase on average which is evident from the data concerning legal entities. The countrywide average value of donations per one taxpayer is stable and has a higher value than that of individuals. The comparison of the Moravian-Silesian region, which exhibits companies' greater involvement in relation to donation, is remarkable.

The existing tax credits represent a positive aspect in the tax law, but merely this will not provide more financial resources for NGOs. Tax benefits are not such strong impact on incentives to corporate and individual commitment. However, they may affect the amount of donations, especially in smaller companies and major individual donors.

As revealed from the research, tax deductible donations are used by a relatively small number of taxpayers, both individuals and legal entities. The form of a single donation is used rather for individual donations in the Czech Republic. This indicates the need to build a base of individual donors for the non-profit sector which would become a stable source of income.

It is apparent from analysis performed that the state policy in the Czech Republic could encourage a long-term approach to philanthropy more and could strengthen areas that become a priority for some reason, or they have long been underfinanced. From the above, it can be concluded based on the situation in the Czech Republic that the barrier to the financing of NGOs from private sources represents, in addition to a lower amount of donations, their one-off in particular.

Altogether, the welfare state strives for social justice. It is impossible to eliminate all social inequality, but it is possible not to place obstacles and, in the best case, endorse selected practice to achieve the effects of fair distribution. Taxes in the society fulfil a number of functions in order to promote public policy, for example through the support of philanthropy.

## **ECONOMIC GROWTH AND INNOVATION: MEASURABLE INDICATORS OF ECONOMIC PERFORMANCE**

*Eva Juříčková, Denisa Hrušecká*

### **Abstract**

In general, national innovation performance significantly influences the economic growth of a country. For understanding patents as results of innovation process they must be able to enter national economy and influence economic growth rate in terms of gross domestic product. If not, patents may be on the other hand understood as a barrier of competitiveness what means that they slow down national economy and create negative effects. This article deals with the comparison of national innovation performance of selected world countries that are considered as the most advanced in terms of the number of patents and relationships of above mentioned indicators. Discussion part of this study includes the summary of gained results based on previous research activities. The scope of future research focused on consequent factors of innovation performance influencing the economic growth is outlined at the end of the article.

*Keywords: patent, patent application, economic growth, gross domestic product*

JEL Classification: M21, O47

### **1 INTRODUCTION**

There is no doubt that economic growth is based on knowledge economy. Innovation and new technologies itself are the key factors of an economy and stimulate its growth. The analysis of the most developed world economies shows that these economies also achieve great results in the field of innovation. They are leaders of innovative activities.

From the viewpoint of knowledge management, technological progress is a determining factor of growth and innovation performance. According to study of Romer (1990), the technological change is key factor of income and economic growth of the countries. Other studies following Romer (Slobodyan, 2007, Arnold, 2000; Lau and Sin, 1997; Tamai, 2009 and many others) developed his model into different variants and modified it to present conditions and changes in conditions. This model identified key factors important for complex technological change followed by economic growth basically. The influence of innovation performance is further evolved in study of Galindo and Méndez (2014) who analyzed feedback effect between innovation, economic growth and entrepreneurship. The study works with Schumpeterian model and confirms positive interaction between innovation and entrepreneurship. The authors also confirmed a driving force of these factors leading to economic activities and ending into economic performance. The positive effect of these elements is also supported by studies of Bel (2008), Kim et al. (2011) and Hasan and Tucci (2010).

This paper focuses on interaction of innovative activities and factors presenting an economic growth of the most innovative countries in the world. The part of this study also discusses a situation in patent activities of these innovative leaders and considers a context of solved problem in further influencing factors. The main aim of this article is to show basic calculations of applied patents trends compared to economic performance of leading economies in the world.

The paper is structured as follows: following this introduction, Section 2 offers a theoretical background and literature review. Section 3 explains the methodology and data sources used. The main results are presented in Section 4, and discussed in Section 5. Section 6 offers the main conclusions of the study and explains the limitations of the analysis.

## **2 THEORETICAL FRAMEWORK**

The question of economic growth is very complicated and hard to answer. Many factors have been influencing this very important indicator of economy condition and entrepreneurship. It is not easy to identify main elements influencing entrepreneurship and competitiveness and determine definite factors of the economic growth. The heart of the running and growing economy must be innovation and technological change. The definition of innovation is not explicitly given. The definition of Statistical Office of the European Communities (2005) explains innovation as the implementation of a new or significantly improved product (good or service), or process, a new marketing method, or a new organisational method in business practices, workplace organisation or external relations. Valenta says (2001), any change in the industrial structure of the industrial production organism will be regarded as an innovation. This technical concept includes all factors which have impact on innovation and constitute it as well. Valenta explains innovation as a complex process jointed with change in innovation factors and their impact to orders of innovation classification. According to Schumpeter (1934) the innovation is the critical driver of economic growth and depends on knowledge, creativity and further factors (Popescu at al., 2012; Williams and McGuire, 2010 and Vaz and Nijkamp, 2009).

As we understand innovation as a result of innovation process, the final output is possible to measure as an indicator of innovation activities. We analyse this indicator of innovation performance from macroeconomic point of view and compare it to economical factor reported by selected countries and obtained from accessible databases.

### **2.1 Economic growth and performance**

Economic growth of a country represents its increasing economic performance. It is influenced by many factors. One of them is innovation performance. Based on all available studies, noticed in the text below, innovation can be considered as a major source of technological progress, economic growth and growth of living standard.

According to Popa and Vlasceanu (2013) the innovation is described as an important factor and option for economic growth, Batabyal and Nijkamp (2014) studied a role of innovation in a Schumpeterian model of economic growth. The clear role of innovation in economic models shows us a correlation of these two macroeconomic indicators.

### **2.2 Patent activity as a measurable indicator**

There is a lot of indicators that can be considered when comparing innovation performance of individual countries. One of them is a number of patents. If patent is understood as a result of innovation process and realised idea, it is possible to identify with the definition of World Property Intellectual Organization which characterises invention as a product or a process that provides, in general, a new way of doing something, or offers a new technical solution to a problem (WIPO, 2015a). Afterwards, this activity requires some kind of protection in form of the highest level of legal barrier – patent. From the macroeconomic point of view, number of patents is considered as an indicator of innovation performance which is securely comparable with other macroeconomic indicators.

## 2.3 Hypothesis

The literature review leads us to following hypothesis:

H: The innovation activities of companies lead to higher economic growth and better results in economic performance of selected countries.

This hypothesis is based on assumption of close correlation between applied patents as a result of innovation process of companies and economic growth of particular country as a macroeconomic indicator of economic performance.

## 3 METHODOLOGY

In order to compare indicators between different countries, it is necessary to set up absolutely transparent and clear indicators and define limitations for statistical purposes. It is very difficult to explain the innovation as a product result or process output; the meaning could be understand in a board sense of the word from the different point of view.

For the purpose of this paper this very broad concept of innovation had to be defined more precisely. We understand innovation as a final output of innovation process which should be specific and definable. It is offered to use an appropriate database of comparable results of country's innovation performance. The data set was constructed from several number of sources.

### 3.1 Definition of sample data

For purpose of this study we make use of patent database to get relevant, comparable and measurable parameters of innovation performance. So the panel of data was obtained in World Intellectual Property Organization database, of which mission is to lead the development of a balanced and effective international intellectual property system that enables innovation and creativity for the benefit of all (WIPO, 2015b). Patent data of WIPO are obtained from national patent offices and we decided to analyse results of the five best countries in patent application statistics, based on rank in 2013.

Panel data from 5 countries (Germany, China, Japan, Republic of Korea and United States of America), for the period of 2004 to 2014, has been ordered to the best results in 2013 and present almost 79% of applied patents worldwide. Tab. 1 shows basic data for analysis, noticed in period of 2004-2013.

The increasing trend in patent applications shows us the importance of innovative activities in selected countries. Displayed data show a large gap between innovative leaders presented by China and the United States of America and rest of countries in top five world's innovators, more information in Table 1.

Tab. 1 – Trend in patent applications for top 5 world offices. Source: Economics, 2014

Year	Germany	China	Japan	Republic of Korea	USA	Total
2004	82 280	130 384	423 081	140 115	356 943	1 574 400
2005	84 020	173 327	427 078	160 921	390 733	1 702 900
2006	85 461	210 501	408 674	166 189	425 966	1 791 200
2007	86 175	245 161	396 291	172 469	456 154	1 876 900
2008	89 077	289 838	391 002	170 632	456 321	1 929 200
2009	84 695	314 604	348 596	163 523	456 106	1 861 700
2010	86 599	391 177	344 598	170 101	490 226	1 996 800
2011	85 674	526 412	342 610	178 924	503 582	2 157 900
2012	88 625	652 777	342 796	188 915	542 815	2 356 500
2013	89 743	825 136	328 436	204 589	571 612	2 567 900

The next source, which was used for comparison, is database of Organisation for Economic Co-operation and Development (OECD) which includes economic results of its 34 members – the most powerful world economies. Gross domestic product per capita was used for comparison in order to achieve results by work force, not just by economy size and structure. The analysis was based on data shown in Tab. 2. This table displays GDP of these countries and stable trend in its development. GDP of China increased from 4 362 US dollars per capita in 2004 to 12 247 US dollars in 2014. The growth is almost 280 %, China is the country with the fastest GDP growth in this group.

Tab. 2 – Gross Domestic Product, total, US dollars per capita. Source: OECD, 2015

Year	Germany	China	Japan	Republic of Korea	USA
2004	30 668	4 362	29 384	22 968	41 857
2005	32 144	5 015	30 446	24 220	44 237
2006	34 672	5 886	31 795	25 863	46 369
2007	36 737	6 685	33 319	27 872	47 987
2008	38 378	7 458	33 500	28 718	48 330

2012	42 730	11 126	35 501	32 022	51 435
2013	43 108	12 247	36 069	33 062	52 985

### 3.2 Statistical methods

We compared data achieved across the countries and made basic statistical calculations to get details about situation. The baseline equation includes mean and middle value of monitored indicator and its percentage in total value. Then we follow trends in indicators and increasing values in number of applied patents.

In a body of literature there are many theoretical works researching and comparing this area in detail. The study of Zekos (2014) analyses influence of patents on GDP and economic growth, Biglu (2010) investigates the relation between selected countries and patent applications used linear correlation as a statistical method. This study confirms a hypothesis of close relationship a give us a data about regression coefficient and tightness of these factors interdependence.

Statistical calculation in detail we expect in our other study which will be done in a context of more innovation performance indicators. The indicators will be understood as broad factors based on OECD statistics and World Bank data mostly.

## 4 MAIN RESULTS

### 4.1 Patent application and its trend in selected countries

In result part of our paper we would like to present basic calculations of researched area. We see in Fig. 1 trend in number of applied patents in the best ranked countries.

Fig. 1 – Number of applied patents in selected countries. Source: Authoress’s elaboration based on data from Economics, 2014

As we see in a graph, the number of applied patents increased from 2004 to 2013. The highest level of this indicator was noticed in China, United States of America was placed in the second position. These two countries we can consider as leaders and countries determining future development of this indicator. Their position is absolutely ingrained.

Basic calculations show us the mean, middle value and standard deviation are displayed in Tab. 3.

Tab. 3 – Patent applications in selected countries and basic statistical calculations. Source: Authoress’s calculations based on data from Economics, 2014

Country	Mean	Middle value	Standard Deviation	Max	Min	Standard Error
Germany	86 235	85 925	2 238	89 743	82 280	707,57
China	375 932	302 221	214 077	825 136	130 384	67 697,00
Japan	375 316	369 799	35 696	427 078	328 436	11 288,08
Republic of Korea	171 638	170 367	16 265	204 589	140 115	5 143,45
USA	465 046	456 238	62 044	571 612	356 943	19 620,00

It is shown in Fig. 1 and Fig. 2, the trend in Germany has not changed during the selected period. China noticed very dynamic increase in a number of applied patent. In 2004, Chinese applicants submitted only 130 384 patents to patent office, but the trend turned to 825 136 applications in 2013. China became a leader in patent and innovative activities in the world in 2011. The USA were skipped over in ranking and took the second position almost with 600 000 patents.

Fig. 2 presents statistical data calculated Tab. 3. We see amounts of average values gained by particular countries and calculations of standard deviation. It is evident that Chinese results are scattered and the speed of increasing of this indicator is growing up. Noticed variance between values is huge during the period of 2004-2013, see minimum and maximum values, displayed in Tab. 3.

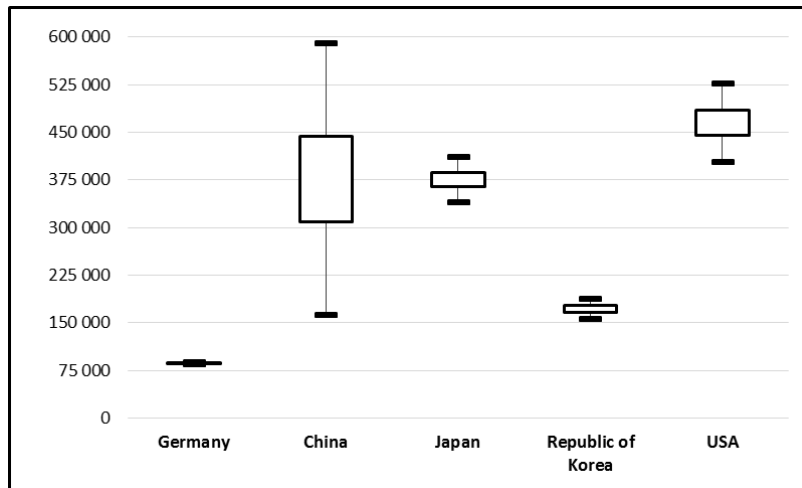

Fig. 2 – Statistical calculations graphically displayed. Source: Authoress’s own calculations based on data from Economics, 2014

These result shows us how the position of China has changed in last 5 years. China became a leader in patent application very fast also driving force of worldwide increase in this area of innovation performance. The position of China is going strengthen and this country is becoming a leader in intellectual property indicators for further years. This data we have to understand in a wider context of Chinese patenting system of technical inventions. Patents are also granted to non-technical inventions which do not correspond to generally accepted definition of innovation and it is very easy to obtain it. Up to 40 % of patent applications is usually granted and the patents used to be granted without any detailed analysis of patent origin.

#### 4.2 Statistical analysis of GDP as an indicator of economic performance

Gross domestic product is the second indicator of our analysis. As it is displayed a trend of increasing GDP for selected countries in a period of time, see Fig. 3.

Fig. 3 – Gross domestic product per capita. Source: Authoress’s own elaboration based on data from OECD, 2015

It is noticed in a graph, that USA is a leader in economy's productivity. The trend has increased since 2004 and is stable. Germany is placed on second position, Japan on third position in this category. China closes this rank of five most innovative countries in the world. Gross domestic product per capita in China is on lowest level of all selected countries in our study. This we have understood with problems of educated human capital in China, internal problems of market economy and other factors influencing economy together with future growth perspective.

Statistical calculations of this indicator are displayed in Tab. 4

Tab. 4 – Gross domestic product in selected countries and basic statistical calculations.  
Source: Authoress's calculations based on data from OECD, 2015

Country	Mean	Middle value	Standard Deviation	Max	Min	Standard Error
Germany	37 717	37 730	4 105	43 108	30 668	1 298,21
China	8 015	7 882	2 484	12 247	4 362	785,40
Japan	32 994	33 410	2 016	36 069	29 384	637,60
Republic of Korea	28 491	28 556	3 184	33 062	22 968	1 006,96
USA	47 817	48 147	3 086	52 985	41 857	975,80

Tab. 4 shows average values of all selected countries. USA reached the highest average value from all considered years, namely 47 817 US dollar per capita. There are not significant differences between minimum and maximum values. The table also shows that US economy reaches quite stable results while China (which can be considered as the weakest economy according to this indicator) increases its growth rate. All other countries reached relatively stable economic results without any significant deviations in considered values.

Fig. 4 presents a graph of calculated statistics information. Source: Authoress's calculations based on data from OECD, 2015

Figure 4 includes graphical interpretation of gained results which also illustrates relatively stable values of this indicator with low level of standard deviation. You can see really small differences between lowest and highest values.

## **5 DISCUSSION**

The obtained results clearly show an increasing trend in the number of patents in all considered countries. Countries, which lead ranking of innovation performance, have accelerated growth rate of this indicator and reached more than 80 % of total number of patents applied in 2014.

Number of applied patents of selected countries is increasing faster and faster year by year and confirms growth of innovative activities and their role in performance of economies. The study of Iwaisako and Futagami (2013) investigated an influence of patent protection in an endogenous growth model and its effect to capital and economic growth. They confirmed that the stronger patent protection raises innovation and has positive effect to economies. If we understand patents as an innovation protection, the relationship among these two indicators is done and influenced by tightness of itself dependence. Frietsch at all (2014) examined the linkage between patenting behaviour of selected countries based on level of technology knowledge compared to their economic success in international markets. They confirmed very strong correlation between these two indicators and sense of innovative activities protection. Patent rights and economic growth were studied by Hu and Png (2013), who established the hypothesis that stronger patents rights lead to faster growth in higher-income countries. They connected this effect to accumulation and raising productivity of industrial economies.

If we compare data of analysis, we confirm a dependency of these two parameters of economic performance. The economic growth of china has really huge impact to patent activities of this country. Development of trade with China puts pressure on patent applications that are not internationally acceptable and need to be registered separately by Chinese patent office. The comparison of individual structures of applied patents according to their owner shows that the majority of applications are submitted by residents what is related to China's trade policy. The increasing Chinese investment in science and research confirms its growing trend in innovative activities and awareness of the importance of technological progress and productivity improvement. This Chinese policy is compatible with economic growth of this country, expressed in total values compared to growth rate. Despite of a problem with patent policy and open market economy in China, it exists close correlation between these two factors. Political and economic situation in China initiate a pressure on patent activities on new inventions in connection of production changes from simple job activities to production high added value.

Along with China's awareness of the importance of protecting results of their research, development and innovative activities USA achieve continuous growth of patent protection. USA as a leader of global progress shows a steady increase in the number of applied patents in response to the economic results. The comparison of the structure of patent applications confirms the importance of non-residents investment and patents applied abroad. It refers to the stability of economic growth and attractiveness of US economy for foreign investment. Despite the problems related to economic crisis the United States has become the guarantee of return on investment with a quality system of intellectual property protection what attracts investors and make innovation growth stronger. Regardless of all actual problems of US economy, it is still one of the most developed world economies in the field of innovation. It reaches stable growth of innovation activities, innovation environment and investment in science and research activities.

From the European perspective the most comparable results are achieved by German economy. Germany is the only one from all European countries that is able to keep up with world leaders. It reached fifth position in gross domestic production (in absolute values) in 2014. The German innovation performance is stable and it determines the growth of economic

performance in Europe. Around 80% of owners of applied patents are residents – German owners requiring legal protection of their technical inventions. On the other hand, it is unquestionable that economic and innovation performance are influenced by more factors than just basic performance values. A limitation of this study lies in the incompleteness of the problem which should also consider the influence of human resources, level of technology, investment in education, access to capital and financial resources for innovation etc. The above mentioned factors significantly affect innovation activities of companies and influence economic performance as well. However, this study is not focused on describing the whole problem. Its goal is only to highlight the interdependence of selected parameters and their importance for solved problem.

## **6 CONCLUSION**

In this study we shown a relationship between two indicators of motors of selected economies, ie. applied patents and gross domestic product as an indicator of economic growth, in a period of 2004 to 2013. We confirmed results of other studies which compared economic development and technology from data on patents (Ortiz-Villajos, 2009; Zeira, 2011; Chen and Iyigun, 2011). Our approach is based on basic data from OECD and WIPO databases and hypothesis that innovation activities of companies lead to higher economic growth and better results in economic performance of selected countries.

As we see in a study, the main results show us the relationship between considered indicators based on simple comparison of gained results from the viewpoint of economic growth.

Despite the fact that the results of this study confirm positive relationship of examined indicators, the other theory can understood innovations as a barrier to the new technological discoveries what slows down economic growth.

It is understand as a legal dogma today's approach of patent owner to use the patent protection. In reality, it is impossible to use the knowledge, protected by patent, for higher exploration and development of innovation. Are patents barriers of innovative activities and economic growth? This idea is connected to global inventions and growth of economies compared to protected knowledge and prohibited areas of new changes and cognitions. This question is asked to further research of innovative activities blocked by barriers and further factors influencing innovation process. This assumption is for further study and deeper analysis.

## **MOBILE BANKING IN THE CORPORATE SEGMENT OF THE CZECH BANKING SECTOR**

*Blanka Kameníková*

### **Abstract**

The aim of this article is to evaluate the current importance of mobile banking in the Czech banking sector, namely in the corporate segment and the possible influence of mobile banking busage on the customer satisfaction and subsequently on the financial performance of a bank. After the general theoretical study of the issue, realised by review of current research papers available, the study tested the level of mobile banking usage and satisfaction with this service in the corporate segment. For this purpose, we distributed a survey among 251 of Czech companies. Research proved that the overall level of usage of mobile banking is 21 % among companies. Companies are overall satisfied with mobile banking, when they use it. The most important reason, why companies do not use mobile banking is overall satisfaction with services provided via general communication channels. The survey results are accompanied by a market study of the current mobile banking applications available in the Czech Republic, focusing on their functionalities, specific features and price conditions.

*Keywords: Mobile Banking, Security, Corporate Segment, Customer Satisfaction, Cross-selling*

JEL Classification: G21

### **1 INTRODUCTION**

As the usage of mobile devices, such as smart phones and tablets has increased dramatically in the last few years, it has influenced many areas of one's everyday life, banking including. The ubiquitous presence of the Internet means people can, and are willing to, manage their financial issues much easier than they did in the past, even easier than with the online banking (using personal computers or laptops). According to the Board of Governors of the Federal Reserve System (2013), mobile banking can be defined as a sum of services allowing consumers to obtain financial account information and conduct transactions with their financial institution. It does not provide customers with the full range of services as the online banking or visiting the branch do, but the number of services available in their mobile version is growing. The most frequent activities in mobile banking are checking account balances, requesting a cheque book, sending payment reminders or viewing the last transactions. Since more and more people are using mobile devices, the potential of mobile banking is huge. Nevertheless, there is also a question of security. Many people do not use mobile banking because they do not trust in it. However, the security itself is not a problem; it is more about the customers' feelings. Thus the main challenge for banks in the coming years is to educate their clients and show them mobile banking is secure. In fact, there was about the same fear releasing online banking and in the end it has turned into the favourite distributional channel for many customers. The reason why banks should pay attention to mobile banking is that it can boost the customer satisfaction and thus cross selling to them. As a result, banks can improve their financial performance adapting to mobile world trends.

## **2 THEORETICAL BACKGROUND**

### **2.1 Smartphone usage as a prerequisite of mobile banking**

The potential of mobile banking is based on the usage of mobile phones, namely smart phones. These gadgets are being widely used by the majority of people in developed countries, such as the USA, Europe or eastern Asia. Many papers, e. g. that of Rooney (2013), Board of Governors of the Federal Reserve System (2013) or ING (2013), show the spread of smart phones has increased dramatically in the last few years. That is the first prerequisite of the mobile banking success. In the Federal Reserve System's publication, 37 % of consumers indicate that getting a smartphone was the main reason why they started using the mobile banking (Board of Governors of the Federal Reserve System, 2013).

As the use of mobile banking increases, mobile phones are also becoming tools for managing personal finances and controlling spending. For example, 64 % of mobile banking users report using their mobile phone to check financial account balances or available credit before making a large purchase in the past 12 months. Of those who checked their balance or available credit, 53 % report that they decided not to buy an item because of the amount of money in their bank account or the amount of available credit. Since so many consumers have almost constant access to their mobile phones, these devices have the potential to provide proper information likely influencing consumer financial behaviour and help them to make different, and perhaps smarter, financial decisions. The actions consumers take in response to the receipt of text message notices from their financial institutions demonstrate some of the potential effects of this technology for encouraging consumers to engage in different financial behaviours that may in the end prove to have beneficial outcomes (Board of Governors of the Federal Reserve System, 2013).

According to The Wall Street Journal, Europe is projected to dominate global smartphone penetration by 2017. Seven of the top 10 countries by penetration will be in Europe (in order: Norway (1), Denmark (2), The Netherlands (3), Sweden (4), Finland (6), the U.K (7). and Germany(9)). South Korea (5), Australia (8) and Japan (10) are the only non-Europeans to break in, whereas the U.S. is 11th. Furthermore, only three countries are predicted to achieve more than 90% penetration and all are European — Norway, the report claims, will have achieved 97.6% penetration by 2017. In the same year penetration in the Middle East and Africa will be only 37%. However, even though the relative penetration in Europe is supposed to be the highest, the Asia-Pacific region is expected to dominate the smart phone market in raw numbers. The analysts predict that while the region currently outsells Europe by about 500 million units (609 million units to 125 million units), by 2017, the Asia-Pacific region will be selling almost a billion more devices (1,266 million to 277 million), and will account for almost half of all smartphones sold globally (Rooney, 2013).

### **2.2 Mobile banking current usage**

According to a survey conducted by ING last year, mobile banking is getting more and more attention among customers. The results of this survey show more than a third (37%) of almost 12,000 internet users surveyed in 12 European countries is already using mobile banking. The biggest share of Internet users who use mobile banking is in Turkey (49 %), Spain (44 %) and the Netherlands (44 %). The major reason why respondents use mobile banking is that it allows to better control their money issues: 84 % say they check the account balance more often, 73 % have more control over spending and 62 % say they pay bills on time more often with mobile banking. It means banking on the go helps people control their accounts more effectively. This survey also suggests mobile banking is going to gain even more popularity in next few years: the uptake of mobile banking is stronger for under 35s, and for people

frequently using social media, which are the groups seen to indicate future trends. Thus, the usage of mobile banking is expected to grow. (ING, 2013)

Similar data is available for the United States. Nearly 28 % of mobile phone users in the survey of the Federal Reserve System report that they used mobile banking in the past 12 months. (Board of Governors of the Federal Reserve System, 2013) Although the number is lower than the current usage of mobile banking in Europe, it cannot be compared that easily. Firstly, the methodologies of the surveys of the Federal Reserve System and ING differ. Secondly, the ING survey was carried out more recently, i.e. by now the current usage of mobile banking in the U.S. could be actually higher than in Europe.

As for the age structure of typical mobile banking users, Samaad (2014) states 57 % of Generation Y use mobile banking. The ING research (ING, 2013) has found out the age group most using mobile banking is the one between 25 and 34 years. 50 % of respondents in this group stated they use mobile banking (46 % of people aged 18-24 and 44 % of people aged 35-44). Finally, the Federal Reserve System's 2012 survey show individuals between ages 18 and 29 account for approximately 39 % of mobile banking users, whereas this age group represents only 22 % of all mobile phone users (Board of Governors of the Federal Reserve System, 2013).

The Federal Reserve System's study also states that the usage of mobile banking is generally not related to a household income. On the other hand, it is supposed to correlate with education. 72 % of mobile banking users have at least college education, which is far more than their 60 % share of all mobile phone users. As for the frequency, a reported median is 6 times a month, whereas the share of mobile bankers reporting that they used it more than 10 times per month increased to 35 % (Board of Governors of the Federal Reserve System, 2013).

### **2.3 Security Dimension**

However, Yoon and Occeña (2014) also point to the fact that consumers have shown reluctance to complete simple online transactions due to security concerns and perceived risk, which is posited as a critical obstacle to consumer acceptance of Internet banking. Therefore, despite an increase in the number of Internet users and advantages of Internet banking for customers, the growth rate of those who adopt Internet banking has not risen as strongly as expected. Therefore, they expected that customers' perceived security negatively influences mobile banking use with a smart phone. The most common banking activities available at smart phones are retrieving an account balance, transferring money between a user's accounts, and making a payment.

Authors as well state that in the context of mobile banking, threats can be made either through network and data transaction attacks or through unauthorized access to the account by ways of false or defective authentication. Rose (2012) adds another common technique that is called "repackaging." This means hackers take a legitimate app, modifying it to include malicious code and then republishing it to the app market or alternate sites. This usually works because the average user cannot tell the difference between the legitimate app and the modified malicious version. Sometimes the hackers will even take a paid app, modify it to include malicious code and then offer it for free. The user, thinking it is the legitimate trusted app will grant the app permission to access various system resources which allows the malicious code free reign over one's device.

Consequently, consumer-perceived security might be concerned with many issues from financial losses to privacy problems. Yoon and Occeña (2014) argue the Internet banking using a smart phone tends to be more vulnerable to malicious attacks than the regular Internet

banking using a personal computer. In order to prevent security problems, advanced techniques including strong authentication procedures, encrypted transactions, and privacy seals can be considered for utilization in Internet banking systems.

Rose (2012) has found out that the software of mobile devices could be problematic itself. Some 76 % of the apps tested actually stored cleartext usernames on the devices, and 10 % of the tested applications, including popular apps LinkedIn and Netflix, were found storing passwords on the phone in cleartext. The security testing on Apple and Android in multiple categories, ranging from social networking applications to mobile banking software found that Apple's iOS based apps consistently scored higher marks than Android apps in security tests. This is because Apple's Keychain security architecture for storing user credentials is supposed to be stronger than Android's Account Manager System.

Also the study of Board of Governors of the Federal Reserve System (2013) concludes the security is a big issue for bank clients. In their survey, consumers reported less confidence in the security of mobile banking and payments technology in the 2012 survey than they did in the 2011 survey. In 2011, approximately 38 % rated the mobile banking service "very safe" or "somewhat safe". In 2012, the share reporting that mobile banking was "very safe" or "somewhat safe" declined to 34 %. The share of consumers indicating that they "don't know" how safe it is to bank with a mobile phone rose from 33 % in 2011 to 40 % in 2012.

However, there are authors arguing that the security of mobile banking is just the same as the security of other distributional channels. For instance Srivastava (2013) suggests that security issues in the minds of customers are here only because of their lack of awareness about this facility. All the messages originating from mobile banking applications are encrypted end to end using 128-bit AES encryption, i.e. passwords are protected up to 128 words. Another method to boost the security is account masking. This technique blocks users from seeing full account numbers. According to Srivastava, there is no solid empirical evidence that the mobile banking is a bigger threat than anything else.

In the Czech banking sector, the main regulating authority- the Czech National Bank, deals with the electronic banking security. Its webpages contain information about the potential threats of electronic banking and provide all clients with advice on how to use the electronic banking in a safe way. (Czech National Bank, 2014)

## **2.4 Benefits of mobile banking**

Various authors, such as Andera (2012), Srivastava (2013) or Samaad (2014) agree on these benefits to be the most important: faster transaction speed, little to no cost for transaction fees, and increased information transparency.

Andera (2012) also pointed out that the Federal Reserve Bank's study, Consumers and Mobile Financial Services, released in March, 2012, stated that the most common use of mobile banking - by 90% of mobile banking users - is to check account balances or recent transactions. Transferring money between accounts is the second most common use (by 42% of users) of mobile banking. But within that total number of online visits, the portion that comes from mobile phones and tablet devices has grown dramatically - by 269% from 2010 to 2012.

## **2.5 Pitfalls of mobile banking**

One reason for not using mobile banking is clear; it is the above mentioned security. According to the ING survey, 33 % of respondents who are not currently using mobile banking say it is because they find mobile banking not secure enough. However, the main

reason for not using mobile banking is that people do not possess the proper technology (i.e. a smart phone or tablet). 37 % of respondents stated this. Only 11 % of respondents say they are not using mobile banking because they can meet their needs easily without interacting in mobile way. (ING, 2013)

## **2.6 Mobile banking for corporate segment**

According to the paper of Stuhldreher (2010), just 5 % of small business owners have used a smart phone for banking functions such as paying bills, but a majority expresses interest in doing so. Mobile services are handy in general, and especially when transactions require dual approval. Such cases typically require a senior executive to sign off on transactions prepared by lower-level employees. With mobile banking, an alert can be sent to the executive's mobile device when a transaction is ready for review. That means he or she can be elsewhere handling other matters without the risk of delaying an important transfer of funds. Small business owners are a natural market for mobile banking because of the convenience factor. They have so many responsibilities to juggle that quick, easy banking becomes a way to manage their time more efficiently and thus an important priority.

## **2.7 Paying for mobile banking?**

Hernandez (2009) opines that though financial institutions have not charged their customers for online or mobile banking, some small-business owners might be willing to pay for such services. This opinion is based on a survey done by Aite LLC (Boston) on a sample of 283 U.S. small businesses. Roughly 50% of surveyed small-business owners stated it would be acceptable for financial institutions to charge fees for some online and mobile-banking services, states the report. Specifically, 27% of respondents would be willing to pay for mobile-banking services, 35% for remote-deposit services and 31% for electronic invoicing. Of the respondents willing to pay for mobile-banking capabilities, 15% would be willing to pay between \$5 and \$10 per month, 3% would pay between \$11 and \$15 per month, 4% would pay between \$16 and \$20 per month, and 5% would pay between \$21 and \$26 per month.

On the other hand, Stuhldreher (2010) suggests that retail customers have come to expect free online and mobile services. Basic corporate banking will likely be free as well, but he agrees that research indicates corporate customers may be willing to pay for advanced functions. Moreover, at present, mobile banking is mostly a retention tool. Business customers are not likely to choose a bank just because it offers mobile banking; although in a couple of years they may abandon banks that do not.

## **2.8 Cross-selling with mobile banking**

Graham (2014) states an interesting example of how mobile applications can boost the cross-selling of a bank. There is an app providing capabilities to search for houses for sales, take and record photos and videos, calculate monthly mortgage payments and finally, connect to a mortgage banker. In such a way a bank is driving more upstream from the transaction element to engage prospects and customers. Moreover, some banks have begun to roll out merchant-funded rewards program, which allows customers to receive coupons from retailers by clicking on offers sent directly to their online banking accounts.

Valentine (2011) adds that mobile banking customers seem likely to be more profitable, and studies are bearing that out. Mobile banking users maintain higher average balances (\$64,303 versus \$59,384) and have higher net worth (\$341,017 versus \$281,263) compared to average

consumers. A customer who actively uses mobile is an engaged customer who a bank can continue to build loyalty with and hopefully cross-sell to.

## **2.9 New trends**

Mobile banking can be considered as a new trend in the banking sector. Thus there are still plenty of opportunities how to bolster its power. According to Belás (2014) the bankers themselves believe the mobile banking will use more mobile devices available, namely cameras, geo location or social awareness capabilities.

The above mentioned survey of ING (2013) also asked respondents about their attitude to social media banking, i.e. carrying out some of the banking activities through social media. Generally, a third of all Europeans (33 %) stated they expect their banks to enable them to make payments through social media. The most agreeing attitude was found in Romania (57 %) and Turkey (51 %). 70 % of respondents expect their banks to give them tips for saving through social media. Currently, customers use social media in relation to their bank for getting general information (39 %), complaining about products and services (32 %) and getting in contact with a bank employee (31 %).

## **2.10 Mobile banking and sustainable growth**

Srivastava (2013) goes a bit further and suggests that in some places, mostly in developing countries, mobile banking can be a tool of financial inclusion and thus a sustainable growth. He defines mobile banking as a secure banking operation by which services of banks like banking, credit card loan, bill payment and pre-paid mobile recharge can be accessed from customers mobile phone anytime and anywhere. According to his paper, rural areas are having enough potential regarding wireless telephone market. If telecom service providers move towards rural market they will get enough business and this can work as a boon regarding financial inclusion too. The results of his research showed that people use mobile banking for these activities: requesting a cheque book (7,5 %), sending payment reminders (7,3 %), seeing the status of cheques/ demand drafts (8,7 %), viewing the last three transactions (11,87 %) and checking account balances (15,9 %). The Federal Reserve System's survey adds locating an in-network ATM, remote deposit capture (i.e. depositing a check by phone) and making online bill payments from a bank account using a mobile phone (Board of Governors of the Federal Reserve System, 2013).

Moreover, there are three different models of mobile banking in different countries:

- **Alternative banking model:** in this model, banks use mobile phone as a mediator between bank and its customer. A customer needs to register his mobile number with the bank. The main functionalities of this model are balance enquiry, alerts, funds transfer etc.
- **Virtual banking model:** here banks have no role to play, i.e. the entire service is provided by Mobile Service providers by acting as a virtual bank. Mobile service providers charge for these services on pre-paid cards or post-paid bills. Mobile service providers use mobile balance too as a virtual currency. This model can as well help in financial inclusion in the third world countries if it is accepted by their central banks by doing proper amendment in banking regulation acts. It is suitable for all banking services.
- **Bank on mobile model:** it is also suitable for all banking services. It is proposed that mobile service providers should have a tie up with banks. Such models of connections already exist in some third world countries, such as India.

## **2.11 Czech banking sector and mobile banking**

As the popularity of smartphones and tablets has been substantially growing recently, all major Czech commercial banks already offer their own applications for these gadgets (for iOS, Android OS and Windows Phone OS). The most innovative bank in this issue was Fio banka, launching its first app for iPhones in May 2011. In August of the same year, it also revealed the app for Androids, and was soon followed by other banks (mBank, Equa bank, UniCredit or GE Money Bank, all of which managed to introduce their apps in 2011). According to Mind Bridge Consulting (2013), users in the Czech republic consider as the most important features of a smartbanking app access security, data transmission security, availability of app for free, account balance and possibility to make payments. The perception of security is noticeably higher if an app allows blocking a payment card in case of loss or stealing. As less useful functionalities were evaluated those which are used rarely, by limited group of users or are available through various alternative information sources. These are for example exchange rates or payment order in foreign currency. The results of the mentioned research showed that the best apps were provided by Poštovní spořitelna, Fio banka and ČSOB. Their applications were the most user-friendly in the comparison of 10 different banks' applications. The basic elements for the evaluation were respondents' subjective evaluation, difficulty of tasks fulfilment, demands on time and number of clicks. On the other side, three banks with the least user-friendly apps were mBank, UniCredit and Equa bank. Although the functions are theoretically the same, the users' experience is what matters in smartbanking apps. The apps have to be fast, easily navigable, safe and not complicated. That is why some of them win competitions even though the apps look basically similar.

The Czech commercial banks are compared on a yearly basis in yet another survey, even more popular, called Golden Coin (Zlatá koruna). In that one, Fio banka won the Golden Coin 2014 in the Online applications category. The jury appreciated above all the fact that Fio banka was the first one in the Czech banking market to offer a smartphone app, free transactions in the Czech republic and Slovakia, possibility to locate the nearest branch or ATM, QR code payments or possibility of priority payments in Euro currency. (Zlatá koruna, 2014)

The specific feature of the Smartbanking of Fio banka is that it offers two levels of access, an open and an authorized one. The first one is open to the public, does not require any login and includes the fees calculator, exchange rates, branch/ATM localisation function and important contacts. The authorised part requires the authorisation of a client and enables to manage their accounts afterwards (payments, transactions, orders, QR codes, cards or patterns). (Fio banka, 2014)

Generally, the apps do not differ much as for the functions offered across the Czech smartbanking market. Almost all of them include account management (payment orders, transaction history, statements, details etc.), QR payments or locating the nearest branch or ATM. However, almost every bank offers some extra service aiming to gain a competitive advantage over all the other banks. In such way, ČSOB offers predictive reading for blind or partially sighted persons and travel insurance arrangement possibility, the portal of Poštovní spořitelna is able to recognise what has been purchased and through this categorisation helps to manage better the family budget, MojeBanka 2 (Komerční banka) also includes the possibility of travel insurance, in the mobile banking of Air Bank clients can use an extra password to authorise payments or can find ATMs of all banks (not only the ones of Air Bank itself), Servis24 of Česká spořitelna enables clients to scan cheques and thus make a payment order in an instant, with mBank P2P mobile payments are possible, the ZUNO app makes

clients able to open a bank account just with their smartphone or tablet and through the app of Raiffeisenbank clients can even apply for a personal loan. (Google, 2014)

As for the price of mobilebanking, the vast majority of Czech banks do not charge any fees for setting or running this service. It is logical: this way to interact with clients reduces the banks' costs (mostly of running a real branch). Nevertheless, some exceptions can be found. Although Česká spořitelna does not require any fee for getting the service, it does charge clients with a monthly fee of 100 or 200 CZK for using mobile and telephone banking. Another bank with the same pricing strategy is UniCredit Bank. The monthly fee for its smartbanking is 100 or 140 CZK for entrepreneurs and firms. (Česká spořitelna, 2014; UniCredit Bank, 2014). Other services, such as sending a confirmation SMS is generally charged in all banks.

### **3 METHODOLOGY OF OUR RESEARCH**

New trends in the banking sector always need more time for publicity and for general subconscious. Especially in the different region of the Czech Republic that is Prague. For those reasons, a questionnaire survey has been used as a method of data collection to analyze usage of mobile banking among of companies in county of Zlin. The questionnaires contained questions on number of employees, years of the company on the market, factors of satisfaction, communication channels and factors of mobile banking.

On the basis of the review of the current theoretical knowledge realised above and experts' estimation, we have formulated these scientific assumptions (SA) and hypotheses (H):

*SA1: Mobile banking is used less than 30 % of companies in county of Zlin.*

*H1: Usage of mobile banking is affected by the size of the company measured by number of employees.*

*SA2: The main reason why companies do not use mobile banking is high concerns about security.*

*SA3: Charging for services would reduce usage of mobile banking.*

Obtained data was analyzed by descriptive statistics and also Pearson's chi-square on significance level is 5 % (0.05).

### **4 RESULTS AND DISCUSSION**

In the questionnaire survey, we contacted a total of 251 respondents, where 28 companies was less than 3 years on the market, 21 between 3 to 5 years and 202 more than 5 years. With less than 50 employees were 190 companies, between 51 – 100 employees 19 companies, 29 companies have 101 -500 employees and 13 companies have more than 500 employees.

Table 1 below gives the results on the level of usage, which is shown as percentage among the companies in the county of Zlin. The results are analyzed according to size measured by number of employees and duration on the market.

Table 1 Overall usage of mobile banking among companies (own source)

Do you use mobile banking?	In total	Number of employees				How long have you been on the market		
		up to 50	51 - 100	101 - 500	more than 500	less than 3 years	3 - 5 years	more than 5 years
Yes in %	21,01 %	26,32 %	10,53 %	3,45 %	7,69 %	32,14 %	47,62 %	17,33 %
No in %	78,99 %	73,68 %	89,47 %	96,55 %	92,31 %	67,86 %	52,38 %	82,67 %
Critical values of $\chi^2$		7,81				5,99		
Calculated values of $\chi^2$		11,02900675				12,4461529		

According to obtained results, only 21 % of companies use mobile banking, which responds to scientific assumption SA1. Also as per the survey, mobile banking is used more than 26 % by relatively small companies with less than 50 employees and also by 47 % of companies, which were on the market more than 3 and less than 5 years.

Statistically significant differences were found, which confirms statistical hypothesis H1 that usage of mobile banking is influenced by the size of the company. Large companies with more than 101 employees do not use mobile banking.

It was also found out that mobile banking is used accordingly to duration on the market.

Reasons, why companies in the county of Zlin do not use mobile banking is shown in the next Table 2.

Table 2 Reasons behind no usage of mobile banking (own source)

For what reason do you not use mobile banking?	In total	Number of employees				Number of years on the market			
		up to 50	51 - 100	101 - 500	more than 500	less than 3 years	3 - 5 years	more than 5 years	
		critical value 7,81				critical value 5,99			
	%	28,87%	30,00%	29,41%	14,29%	41,67%	42,11%	18,18%	27,54%
Security issues	$\chi^2$	3,964300099				2,37854725			
Smartphones and tablets are not used	%	38,66%	37,86%	35,29%	35,71%	50,00%	36,84%	36,36%	38,32%
	$\chi^2$	0,848546494				0,030281362			
Mobile banking app of	%	3,09%	1,43%	5,88%	3,57%	16,67%	0,00%	9,09%	2,99%

the bank does not contain required elements	$\chi^2$		9,268830691					1,959704579		
	%	48,97%	41,43%	70,59%	67,86%	50,00%	36,84%	36,36%	50,30%	
Satisfied without it	$\chi^2$		10,33238186					1,893619223		

Through the obtained results, our scientific assumption SA2 has not been verified. The most important reason, why companies do not use mobile banking is overall satisfaction about 49 % among companies with services provided via general communication channels. Moreover this assumption is strengthened by statistical significance among size of companies measured by the number of employees. That reason was stated by the companies (70 %) with more than 51 and less than 100 employees, respectively 68 % for companies with more than 101 and less than 500 employees.

However, another more important reason than security issue is simple fact that smartphones and tablets are not so common in companies and entrepreneurs do not use them for communication with bank with almost 40 %. Especially in the companies (50 %) which have got more than 500 employees.

Security reasons were provided only by 29 % of companies as key factor why they do not want to communicate with bank through mobile banking. Security question is mostly asked by companies (42 %), which have been on the market for less than three years.

Table 3 Charging for mobile banking and willingness to pay (own source)

Use of mobile banking	Willingness to pay				Total
	yes		no		
yes	22	41%	32	59%	54
no	16	8%	181	92%	197
total	38		213		251

Table 3 is giving us answer on scientific assumption SA3, whether companies would be able to willing to pay for mobile banking services provided by bank. In the survey, companies using mobile banking stated, that they are very satisfied (20 %) respectively overall satisfied (61 %). However there has been strong pressure on banks and their charging policy in the recent years that there has been a logical assumption, that company would not be willing to pay fees for mobile banking.

This assumption was confirmed in the research, where from total of 54 companies, which use mobile banking, only 41 % would be willing to pay for mobile banking. However 32 companies (59 %) stated that they would not like to pay for mobile banking. And 92 % companies, which do not use mobile banking stated, that would not be willing to pay for online service such as mobile banking.

## 5 CONCLUSION

The purpose of this research was to look at usage of mobile banking among companies in the county of Zlin in the Czech Republic. As number of smartphones rises in the hands of the general and mobile banking is considered to become a tool of financial inclusion and thus a sustainable growth. The questionnaire survey was contacted a total of 251 respondents, where

the size and number of employees of the company were used to analyse usage of mobile banking among companies, reasons why companies do not want to use mobile banking, overall satisfaction and willingness to pay for mobile banking services.

The overall level of usage of mobile banking is 21 % among companies in the county of Zlin. That has confirmed our scientific assumption SA1, where mobile banking is used more than 26 % by relatively small companies with less than 50 employees and also by 47 % of companies, which were on the market more than 3 and less than 5 years. The most important reason, why companies do not use mobile banking is overall satisfaction about 49 % among companies with services provided via general communication channels. Moreover this assumption was strengthened by statistical significance among size of companies measured by the number of employees that is why scientific assumption SA2 was not verified.

Research proved that companies are very satisfied (20 %) respectively overall satisfied (61 %) with mobile banking, when they use it. However scientific assumption SA 3 was confirmed, when from total of 54 companies, which use mobile banking, only 41 % would be willing to pay for mobile banking. And 92 % companies without use of mobile banking stated, that they would not be willing to pay for online service such as mobile banking.

## **THE EXCHANGE INTERVENTIONS AS A TOOL OF THE CENTRAL BANK AGAINST DEFLATION IN THE CZECH REPUBLIC**

*Blanka Kameníková, Vanda Nevřelová*

### **Abstract**

Banking sector has always been the area of great interest, but since the outbreak of the global financial crisis in 2007, the focus on this area has been multiplied. As the economies of euro area, as the global economy, robust recovery still have not been seen. The purpose of this article is to examine the effectiveness of how Czech national bank fights against imminent deflation. Among basic monetary policy tools include short-term interest rates, but since these interest rates are on the technical zero from 2012, the Czech national bank could not use this tool to effectively combat the impending deflation. For this reason were used in this struggle the FX interventions. With the use of correlation analysis, we tested the influence of these FX interventions on the macroeconomic indicators, such as inflation and GDP.

*Keywords: central banking, FX interventions, interest rates, inflation, GDP*

JEL Classification: G10

### **1 INTRODUCTION**

Regarding the European economy, year 2014 in eurozone was in the sign of imminent deflation which wasn't averted despite the introduction of different measures, neither economic growth showed a rebound. Among those measures from ECB have belonged cutting its interest rates on the historical minimum, making unprecedented amounts of cheap loans for banks and embarking on asset purchase programs as aim to pumping liquidity into financial system (Morgan, 2014). Imminent deflation was a bogey for the Czech economy as well and because of level of interest rates of the central bank which are on the so called technical zero, the Czech national bank introduced FX interventions in November 2013. Particularly disquieting developments are recorded in European strong economies such as Germany, French and Italy. According to the outlooks, interest rates in euro area are not expected to rise at least to the end of 2015. Weak economic growth, the imminent deflation plus unconventional tools from ECB are the factors which have an impact on those rates (CNB, 2014).

The reason why we deal with this topic from monetary policy is because it is currently a very actual topic. Probably everyone registered the exchange intervention to weaken the Czech crown, which the Czech National Bank underwent in autumn 2013, for the first time since 2002. Opinions on this procedure vary. Representatives of the two major economic institutions (IMF and OECD) agree in their position statement that the CNB was surely correct. By the words of Johann Prader, an executive director representing the Czech Republic in the Executive Board of the IMF: "If a persistent and large undershooting of the inflation target is in prospect, additional tools should be employed. Foreign exchange (FX) interventions would be an effective and appropriate tool to address deflationary risks in the context of inflation targeting framework. This is expected to quickly increase the price level and help increase inflation expectations toward the target". (IMF, 2013) Regarding the exchange interventions, the OECD commented on this in the OECD Economic Outlook as following: „Low demand-side pressures and decelerating food prices are containing inflation pressures in the near term. With interest rates technically at zero and excess liquidity in the

banking sector, the Czech National Bank has started foreign exchange interventions to prevent a long-term undershooting of the inflation target. Foreign exchange interventions should continue until inflation rises into the boundaries of the inflation target range and conventional Monetary policy tools become effective again". (OECD Economic Outlook, 2013)

Even the former Prime Minister of a caretaker government Jiri Rusnok has a positive attitude to exchange interventions. In his opinion, the foreign exchange intervention will help the Czech economy and increase its competitiveness, the weaker koruna is especially helpful for exporters. Interventions by Rusnok should also help the state budget, because higher economic growth was expected and some income taxes are based on the price rise. However the former neither current president are not fans of currency interventions. Former President Vaclav Klaus considers it as wrong and risky step, which has "very questionable effects, but very undisputed costs", which include rising the prices of importation and pressure on the domestic price level. According to the current president of Milos Zeman, the central bank intervention has never helped anything and vice versa they led to losses. Deflation, which is a bogey for the CNB, according to Zeman does not threaten. (Pololánik, 2013)

## **2 THEORETICAL BACKGROUND**

According to Belás (2013) and Revenda (2011) a monetary policy is one of the stabilization instruments of economic policy by which the national bank can ensure and significantly affect the country's macroeconomic balance. For monetary policy in the broadest sense, we can consider the conscious activity of an entity that is through monetary instruments seek to regulate the amount of money in circulation, and thus achieve certain goals. Economists' views on monetary policy are different. Some say that its effect is only short-term (Espinosa, 1998). According to Friedman (1968) behind this conviction is the existence of money illusion and wage (price) rigidities when individual subjects hardly recognize promptly whether it is inflation or the change in real prices. For this reason, the central bank monetary policy can through its unexpected changes in money supply affect short-term cyclical fluctuations in the economy. The most important and at the same time the fundamental objective of monetary policy is to ensure price stability. The central bank's monetary policy deal with the question of what amount of notes is adequate for the needs of the national economy (Mishkin, 2007). From a practical standpoint price stability means that expected changes in the general price level are small enough and sufficiently gradual, and thus do not affect the decisions of firms and households (Revenda, 2011). According to Jílek (2013), instruments of monetary policy represent implementation of monetary policy and operating target of monetary policy is a tactic. Intermediate and final objective of the monetary policy is a strategy. The way in which operational objective effects on the final objective, is called the transmission mechanism of monetary policy. According to Polouček (2009) the monetary policy transmission mechanism is defined as a string of economic ties through which changes in the monetary policy instruments adjustment ponder to changes in macroeconomic variables. At the beginning of the transmission mechanism thus emerge changes in měnovopolitických instruments that change the behavior of intermediate markets, which consequently through another intermediary markets leads to changes in target markets. Their development the central bank wants to influence.

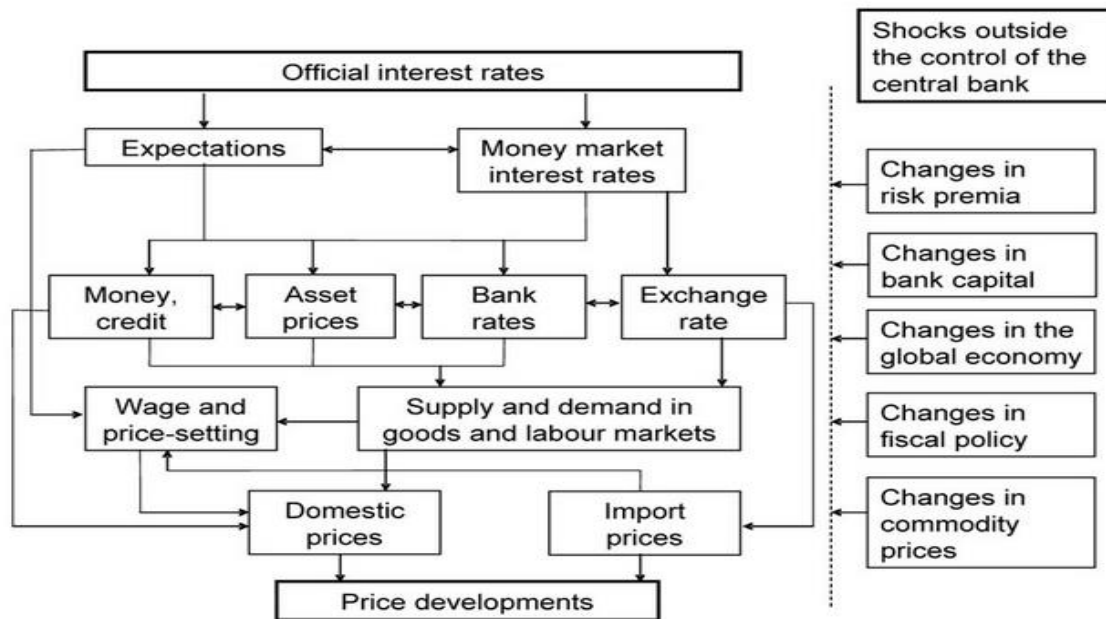

Fig. 1 – Transmission mechanisms of monetary policy. Source: ECB, 2015.

According to Mandel (2008) the process of inflation targeting includes the following system components:

- determination of the inflation target,
- creation of conditional and unconditional inflation forecasts,
- operational management through short-term interest rates of central banks (i.e. repo rate).

Fig. 2 – Inflation target in European Union. Source: ČNB, 2014.

Since January 2010 the ČNB announced a new inflation target as annual increase in the CPI at 2%. The ČNB strives to ensure that actual inflation does not differ from the target by more than one percentage point in both directions. (ČNB, 2007)

Revenda (2011), Polouček (2006) and even Espinoza-Vega (1998) states as the basic monetary policy instrument interest rates in promoting short-term inflation targets money market, because these rates the central bank is able to best affect. As reported by Mandel (2008), until 2002 the CNB published so called conditional inflation forecast. The validity of these forecasts was conditioned by no changes in interest rates of central banks throughout the forecast period. In mid-2002, however, the CNB acceded to the so-called unconditional forecasts, which already include presumed changes in interest rates. Since 2008, the CNB in its "Inflation Reports" started publishing the interest rate path consistent with the inflation forecast in numerical and graphical form. Bank interest rates are derived from interest rates on the interbank market. These in turn react to setting key of interest rates by the central bank. Central bank influences the short-term interest rates by the 2W repo rate, which the central bank remunerated deposits, which has from commercial banks. The higher the rate is, the greater motivation banks have to deposit money in the central bank, instead of lending them to companies and households. The economy will thus get less money and its rate of growth slow down. Another key interest rate of the central bank is discount rate, which remunerated deposits that banks impose overnight. It is also a lower limit for short-term interest rates. The third interest rate announced by the central bank, is lombard rate. It is the interest rate charged by commercial banks for loans, which provide them the central bank overnight. Banks can borrow at this rate usually when the interbank market can no longer borrow.

The use of foreign exchange intervention as an exceptional tool of monetary policy in their work has suggested McCallum (2000) and Svensson (2001) in the context of discussions of the Japanese experience with deflation and its overcoming difficulty. They pointed to the many advantages that using the exchange rate as of unconventional monetary policy instruments has. Of course the biggest risk for central bank is that intervention will not be successful. For example RBNZ (Reserve Bank of New Zealand) několikrát Central Bank unsuccessfully intervened against the growing NZD in the summer of 2007. The NZD had reached new maximums almost every day. Sales of NZD, which RBNZ held, however, only allowed investors to buy NZD at lower levels. Demand for NZD was so great that the market RBNZ literally "roll over". Therefore RBNZ did not achieved its intended targets and spent significant financial resources unnecessarily. (Paez-Farrell, 2007, Bollard & Cullen, 2004)

The potential negative impact of interventions on the monetary base, tmay be sterilized by central bank through open market operations. Sterilized intervention occurs when the operations in the domestic money market and foreign exchange market will compensate each other. If central bank increase the amount of money in circulation through interventions, it can lead to inflation. To compensate each other markets, the domestic central bank must download money from circulation, e.g. by sale of securities to commercial banks. Effectiveness of sterilized intervention is covered by many economists for decades. However, most of empirical studies recorded only weak or no influence between sterilized intervention and exchange rate changes. (Dominguez & Frankel, 1993)

### **3 RESEARCH AIM, METHODOLOGY AND DATA**

The purpose of this paper is to analyze the CNB's monetary policy. For the reason that primary mission of this policy is monitoring and active influence on the rate of depreciation of money, thus inflation, the core of the analysis is to examine the impact of currency intervention of the CNB on macroeconomic indicators, specifically to the above-mentioned inflation. This analysis will be performed by using the tools of statistics, specifically a correlation. The aim of this study is therefore to group, analyze and evaluate data from

monetary policy and its impact on macroeconomic indicators and try to predict the possible future impact of interventions on the Czech economy.

In this study is examined the degree of dependence between the decisions related to the CNB's monetary policy and their influence on macroeconomic indicators. The dependency ratio is examined by correlation analysis in the program XLStatistics while Pearson's correlation coefficient has the following prescription:

$$r_{xy} = \frac{\sum_{i=1}^n (x_i - \bar{x})(y_i - \bar{y})}{\sqrt{\sum_{i=1}^n (x_i - \bar{x})^2 \sum_{i=1}^n (y_i - \bar{y})^2}} \quad (1)$$

Intervention in the foreign exchange market should favor the export trade and the situation in the Czech economy. These measures are supposed to have an impact on competitiveness, profitability and investment capability of Czech businesses. According to the model of the Czech National Bank the hit to exchange rate should create 35,000 job vacancies in the Czech market. According to the objectives of the Czech National Bank the weakening of the crown and holding exchange rate close to the level of 27 CZK/EUR should accelerate a return to inflation of 2%. This target was set by the end of 2014. According to the development of inflation a Governor of the Czech National Bank Miroslav Singer assumes extension of the system of foreign exchange interventions until at least 2016. For these reasons, it is interesting to find out whether there is a correlation between these indicators. These values were compared for the period from 1 January 2013 to 1 September 2014. The dependence of these variables were compared and evaluated through correlation analysis. For investigation was determined the following hypothesis:

H<sub>1</sub>: Inflation is not affected by monetary interventions of CNB.

For analysis of the CNB's monetary policy in the period 2013-2014, we need to start from the date of November 2, 2012, when the CNB cut the 2W repo rate by 20 basis points to a record low of 0,05 %, the lombard rate was reduced by 50 basis points to 0,25 % and the discount rate was lowered by 5 basis points to 0,05 %, as can be seen in Fig. 3. The 2W repo rate has been reduced to the so-called technical zero and therefore it is no longer possible to influence inflation through this tool. (ČNB, 2012)

Fig. 3 – CNB key rates. Source: CNB, 2014.

Fig. 4 shows the evolution of inflation since the end of the year. 2012, when inflation has trended generally downward trend. To fulfill inflation expectations, the CNB introduced as the main deterrent to support its decision the deflation-recessionary spiral, which means the following: If the value of money is increasing, society does not have the propensity to consume, which cause a drop in demand, the companies must lay off, household incomes are declining and companies are pushing prices down. The history shows that deflation is bad tame once it gets going, therefore the CNB decided for prevention than any aftercare. The CNB decided to help fulfill the inflation target of 2 % through currency intervention, since the interest rates were not an effective instrument of monetary policy any longer.

Fig. 4 – Fulfilment of the inflation target. Source: CNB, 2014

Inflation has increased, though, whether this was done due to the CNB is quite different question. The Eurostat data shows that the intervention of the CNB reflected mainly in the evolution of food prices - while in October 2013, food prices in the CR and SR were broadly similar (in October 2013 2,9 % vs. 1,9 %), from November it was otherwise. In SR the first half of last year was followed by a sharp slowdown in food prices, in the Czech Republic the food prices continued in growth, and so the Czech Republic is now the only country in the region where food prices are rising year on year (in SR there is a decline since April 2014).

$$CPI = \frac{P_t - P_{t-1}}{P_{t-1}} \cdot 100 (\%) \quad (2)$$

Regarding the Eurozone, annual inflation in October rose to 0,4 % from 0,3 % in September, which was the minimum for nearly five years. In the EU price growth also accelerated slightly, at 0,5 %. This follows from the final data from statistics office Eurostat.

A year earlier, inflation in the euro area and 0,7 % in the EU was 0,9 %. The rate of growth has long been deeply below level of less than 2 % which the European Central Bank (ECB) has set as a medium-term inflation target.

This gradual move towards deflation strengthens EU problems that devastates the confidence of investors and has a negative impact on the debt burden. Markets can be heard and protest that with short-term interest rates just above zero would be appropriate to to respond more dramatically, as in the US, Japan and the UK.

Prognosis of the year 2014 expected gradual increase of inflation from the third quarter of 2014 and the return of inflation to the 2% target by the CNB in the second half of 2015. In the 2% inflation zone of the CNB's the inflation should keep well in 2016. The CNB announced that using the exchange rate CZK/EUR as an instrument of monetary policy will not be finished earlier than in 2016. On the fig. 5 can be seen inflation in the Czech Republic including the CNB forecast.

Fig. 5 – Headline inflation forecast. Source: CNB, 2014.

The benefits of the weak crown:

- Economic growth has accelerated, all key indicators of condition of the economy have been improved.
- Exports increased, contrary to expectations, the prices of imported food did not increase.
- Positive effect of artificially weakened crown yet has not exhausted
- According to some estimates, the intervention helped increase the GDP by half a percent and reduced the number of unemployed by 10,000.

Risks of the weak crown:

- Prices may start to decline because of cheap oil, sanctions in Russia and excess of food.
- A recession in the eurozone is not excluded, when the ECB has been still vainly struggling with the threat of deflation. (CNB, 2003-2015)

The onset of currency intervention to weaken the exchange rate CZK/EUR can be seen in the fig. 6.

Fig. 6 – CZK/EUR exchange rate. Source: CNB, 2014.

Gradual slowdown in economic growth in 2007 and especially in 2008, has been replaced by more than 4% decline in economic activity in 2009 due to the global financial crisis. The ongoing plight of the global economy and particularly the European economy prevented a faster recovery in 2010. Emerging debt crisis in the eurozone led to a further significant slowdown in economic growth during 2011 and the economic downturn in the next two years, as can be seen from the fig. 7.

Fig. 7 – GDP in the Czech Republic and effective Euro area. Source: CNB, 2014.

Czech Republic is currently very strongly linked to the European Union which leads the Czech National Bank to take account of developments in European Union countries and their monetary policy. The CNB thus mostly “followed” by direction of the European Central Bank but also responds to domestic specifics.

#### **4 RESULTS AND DISCUSSION**

For correlation analysis was used data with changes in inflation depending on the value of the Czech currency against the euro (against the euro for the reason that we are export-oriented country, largely tied to the economy of Germany). Values were used for the last 21 months (from January 2013 until September 2014). Obtained data was converted into the program XLS Statistics. With this program, the values were converted into scatterplot, which indicates

a linear relationship between inflation and the value of currency. This relationship is expressed in the following function:

$$\text{inflation} = -0,837 * \text{hodnota měny} + 23,874$$

The scatter chart in the fig. 8 shows the regression line, which allows to estimate the dependence of the examined variables and their level of changes.

Fig. 8 - scatter chart with regression line. Source: own processing.

To determine the value of the correlation coefficient was used again statistical program XLS Statistics again. The result is given below:

<b>Correlation Coeff</b>	
<b>Correlation</b>	<b>-0,88802</b>

Fig. 9 – Correlation coefficient.  
Source: own processing.

The entire calculation was also verified in Microsoft Excel, both results are identical. The coefficient of determination was also detected while this coefficient reflects the degree of fit of the model and indicates that part of the variability which could be explained by the model.  $R^2 = 0,78858$ , which means that more than three quarters of variance are explained by the regression function, therefore the remaining quarter  $0,21142$  of variance is caused by errors.

Finally, by using of analysis of variance was verified whether there is a statistically significant relationship between the studied phenomena. A null hypothesis was defined (no statistically significant relationship between the quantities exist) and the alternative hypothesis (there is a statistically significant relationship between the studied variables). From the table below (fig. 10), it is clear that the critical value is equal quantile  $F_{1-\alpha}(v_1, v_2)$ , a division of F degrees of freedom, which can be found in the tables,  $\alpha = 0,05$ ,  $F_{1-\alpha}(2, 19) = 3,52$ . Our value F statistic is equal to  $70.8 > 3.52$ . It means that we can reject the null hypothesis. P-value  $0,00000007796$  has a lower value than the significance level alpha of  $0.05$  therefore we can reject the null hypothesis. Among the examined variables there is a relationship.

## 5 CONCLUSION

The aim of this study was to analyze the central bank monetary policy by using the tools of statistics, namely by correlation analysis. At the beginning, one hypothesis was formulated which is related to inflation depending on currency intervention of the CNB. Statistically significant dependence was proved at the defined hypothesis. Thanks to this, therefore, the research has shown that the exchange rate has an impact on inflation.

As mentioned above, short-term interest rates are located at the technical zero from year 2012, therefore the CNB can no longer use them to inflation targeting. To avoid imminent deflation, which would not indicate to economy (which could lead to falling prices and wages and growing unemployment), the CNB decided to use the exchange interventions. However the steps of the CNB are not taken positively from all, as currency intervention can have side and unpredictable effects on the rest of the economy. Given intervention is also quite extensive (in November 2013 CNB purchased about 7,5 billion EUR) and therefore adverse side effects may be higher.

For example, on a server Eurofound.eu (2014) is an article criticizing the CNB's monetary intervention, which, according to the Czech-Moravian Confederation of Trade Unions, seems to be problematic, for example, because it will hit particularly households with low and middle income, because of increased import costs, such as electronics and some food prices. Although households ventured to increased purchases of electronics and other consumer goods after the initiation of interventions, nevertheless it was only a short-term effect, since the pressure for further raise price will dampen household consumption again. The impact of interventions are such that on the one hand, there is an increase in prices of imported goods, which averts deflation and therefore for the CNB it is the fulfillment of its objectives and positive effect, but for households it is a negative, because of a depreciation of their current wealth.

Economic stagnation accompanied Czech economy for five years. The question remains whether currency intervention will not contribute in the longer term to increase our dependence on EU markets. To the Czech economy would help to begin to focus on other territories with rapidly growing economies, such as the Asian country. Fixation of the exchange rate, which is one of the key economic factors, may have except positive short-term results also a negative impact on long-term factors. Movements of economic course are an economic necessity, and therefore experts do not recommend fixated rate for an extended period. In the long run, this fixation is losing his goal and turn causes negative impacts. The CNB presumes to maintain a low rate of the koruna against the euro until 2016. The question is whether interventions for such a long time are still beneficial, but also what happens to

them when the CNB ends with them. What will be the reaction of the markets and how will be downloading excess crown back to the CNB? Because the Czech Republic is a small open economy, these interventions have had a strong impact on export, although smaller than expected CNB. However at the same time these interventions evident in import. If there is a raise the price of imported products, such as fuel and consumer goods, which are important for so energetically and product-dependent country as the Czech Republic is, it will cause a lot of problems in the future. In the short term, many companies and households draws supplies for their production. In the long run, however, these supplies run out, and companies and individuals are forced to buy new goods from abroad at a higher price. Due to this fact the prices of new goods manufactured in the Czech Republic will rise as well, and thus it becomes more expensive even in the context of export. The first year of intervention had a positive impact on our economy. Many economists now criticize the CNB that this step did not have previously. However, this tool is considered to be short-lived. Whether it is a wise decision of the CNB to continue in these interventions, it will appear in the future.

Kalach in his open letter to Singer states that one of the arguments of the CNB is wrong and that is that when it comes to greater consumption by households and firms, and thus provide more space for investment, these investments will lead to industry to modernize production processes and it will be followed by the dismissal of employees (Kalach, 2013). With this we agree, according to our experience and knowledge, we see an effort to minimize the cost and labor costs, and these costs are in each company, if not the greatest, so at least a substantial part of the costs, so companies try to get as much work on the machines and computer programs that control them. Equally he mentioned that you can not increase a demand for goods and services by reducing the value of money, especially when declining purchasing power.

Kohout treats even more detail. He states that price deflation is the result of monetary deflation and that it is in the false correlation with the economic downturn, therefore, they depend only apparently. We have to agree with the assertion that it is difficult to believe that consumers will respond to inflationary expectations by speculative manner. Most citizens do not even know what a deflation means and what the weakening of the crown means, so higher expectations will not affect food consumption, electricity, water, gas, medicines and most other services. Also, we fully agree that the price drop does not result in postponing of consumption. Kohout makes assertion that a price deflation and a decline in GDP is due to monetary and credit deflation. (Kohout, 2013)

In an earlier study, we have encountered a situation in which Milton Friedman proposed a solution, which was based on main thesis of monetarism, the quantity theory of money and their importance for growth and balance of the market economy. He was always for the strict regulation of money in the economy. The main instruments for him were the growth of the interest rates and the growth of the discount rate (restrictive monetary policy). In our opinion, this is one of the cures on inflation, but deflation? After what the CNB cut the interest rates to a minimum, so there was no longer the possibility of using this tool to handle the deflation (which has recently been a major deterrent in the whole world, not just here). Seemingly it would therefore appear that the CNB made the right move, but but has not been another way?

Thus, the solution to which Milton Friedman came in the 70s, when there was a crisis in Japan, according to him, was simple. Bank of Japan must buy government bonds until the amount of money refresh the economy and until it will hold enough power, so that wants the expansionary monetary policy. Friedman also shows how the rates are unreliable as an indicator of appropriate monetary policy. To us this seems to be the right solution, money stay

at home, there is no loss from fall of unstable currencies and there is no redistribution of funds between exports and imports. While the purchase of government bonds could provide enough money to use even fiscal instruments for economic recovery through government spending, they could possibly help revive the economy and even the velocity of money and thus put pressure on inflation.

Current data suggest that the decline in inflation is stopped and the threat of deflation has managed to keep within the limits of sustainability, but was it really caused by the intervention to weaken the crown? Cannot it be that the threat of deflation in the entire EU is now in decline even in those states that did not take intervention? Another fact appropriate to consider we see in marked contrast between the forecasts for inflation and how inflation is actually developed.

## **THE COMPARISON OF LEVEL OF FINANCIAL LITERACY IN FOUR COUNTRIES**

*Liběna Kantnerová*

### **Abstract**

This paper shows the situation of young population educated in financial lectures at Universities in different countries. The knowledge of students was evaluated with the help of questionnaire and statistical methods. This survey was made in the co-operation with some universities in EU, which were co-operative to author's call. Our students will work after their study often in financial departments and manage not only their private finance, but financial budget of the enterprise too. Financial markets have become more complex and individuals are faced with a proliferation of new investment products, many of which are new and often fairly complex. Investment opportunities have expanded beyond national borders, permitting individuals to invest in a broad range of assets and currencies. Financial systems connected with housing become, more and more, an important part of the whole economy. Housing loans will increase, because urban expansion is intensifying.

*Keywords: students, skills, finance, questionnaire.*

## **1 INTRODUCTION**

### **1.1 World**

In recent years lot of countries have become increasingly concerned about the level of financial literacy of their citizens. This has stemmed in particular from shrinking public and private support systems, shifting demographic profiles (including the ageing of the population), and wide-ranging developments in the financial marketplace. As a result, financial literacy is now globally acknowledged as an important element of economic and financial stability and development (INFE, 2009).

Individuals are increasingly in charge of securing their own financial well-being after the retirement. With the shift from defined benefit to defined contribution pensions, today's workers have to decide both how much to save and how to allocate their retirement wealth. Financial markets have become more complex and individuals are faced with a proliferation of new investment products, many of which are new and often fairly complex. Investment opportunities have expanded beyond national borders, permitting individuals to invest in a broad range of assets and currencies. On the other side some banks are too big to fail (TBTF), but in the situation of globalisation the connection of them can start collapse of global financial system (Roubini, Mihm, 2011).

Renaud (2009) emphasises that for the first time in world history more people live in urban areas than in rural areas. As a result, financial systems connected with housing become an important part of the whole economy. Housing loans will increase, because urban expansion is intensifying.

The debate on the links between housing and macroeconomics dates back to Fischer (1933) and his debt deflation theory is opened again in the following statement. Residential capital stock plays an important role in the economy, housing expenses constitute an important part of household expenditures, etc. (Chetty, Szeidl, 2004; Greenwood, Hercowitz, 1991; Skinner, 1994). The relationship between macroeconomics and the housing market has been extensively studied for developed countries (for example: Davis, Heathcote, 2005; Hwang, Quigley, 2006; Seko, 2003; Wen, 2001).

Aside from the “crisis effect”, a series of tangible trends underpin the rising global interest in financial literacy as a key life skill. These can be summarised as follows: risks shift, individual responsibility, increased supply and demand of a wide range of financial products and services (PISA, 2012).

In the USA, the financial situation of today's youth is characterized increasingly by high levels of debt. Between 1997 and 2007, average undergraduate student loan debt rose from \$9,250 to \$19,200—a 58% Family's education was strongly associated with financial literacy, especially if a youth's parents graduated from college. Each of the proxies for family wealth and family financial sophistication were also associated with financial literacy (Lusardi, 2012). 33 % (more than 77 million Americans do not pay their bills in time, only 59 % of Americans have savings and 39 % carry credit card debt from month to month by survey made in 2012 ([http://: finance.yahoo.com](http://finance.yahoo.com))).

Financial literacy, as a new field for a researcher, does not have any determination in the literature sources available. The author will try in the next chart to show, how the negotiation among sciences will look and should be in the co-operation in the solution of any problem connected with financial literacy. Psychology can help in questions of: the choice of methods; which is the best way to influence the media to individuals; how to do parental guidance; how to help any individual in some difficult financial situation; or how to change the financial behaviour of anybody which is not good.

Math is the way to calculate any profit from financial products. It can help in preparing financial plans, and how to choice the best financial product. Its importance is connected with pedagogy, which can find the method to explain and teach children or adults the basis of such a calculation.

The next function of pedagogy is the findingof methods of teaching about existing financial products, their basic functions and dangers, which is connected with the teaching of finance.

Finance describes the different financial products, their functions and methods of using or obtaining profit and increasing the personal wealth of everybody.

Behavioral economics helps in the identification of common ways in the behavior of society in the negotiation of the economy of any country.

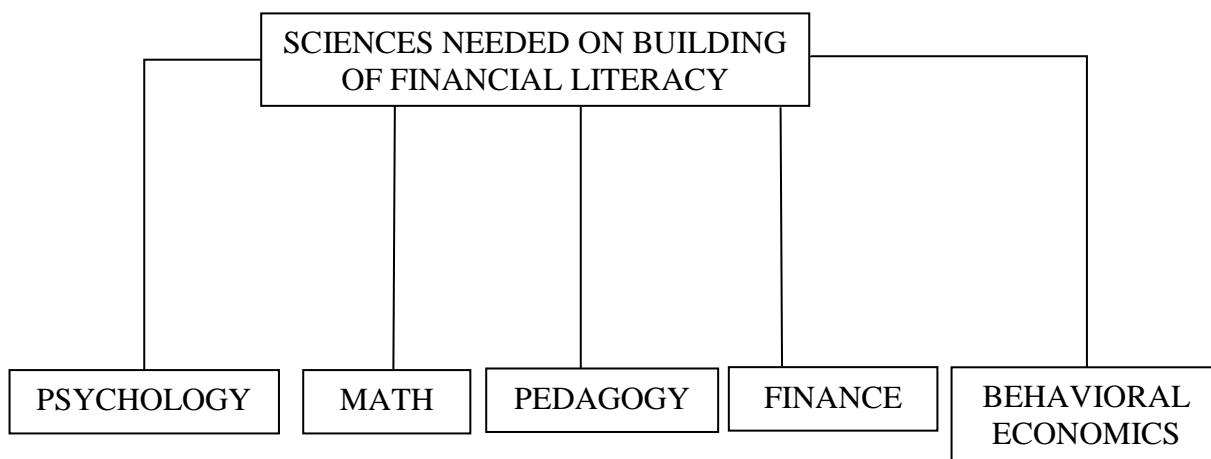

Fig. 1 - Sciences needed on building of financial literacy. Source: own work.

The next chart highlights the negotiation, function and influence among institutions and enterprises connected in the system of one country, their co-operation and influence.

The leader of all should be a government. Their members, through different ministries, should manage the right building of the law system – clear and transparent. For education and the right financial behaviour, the media can be used.

The central bank plays the second most important role. It should co-operate on the creation and function of the law system. The government, through the Ministry of Education, manages the right methods, content and needed results of the teaching of financial lessons. The last role is played by the central banks in financial markets, where they take over responsibility of the right functions of regulatory compliance.

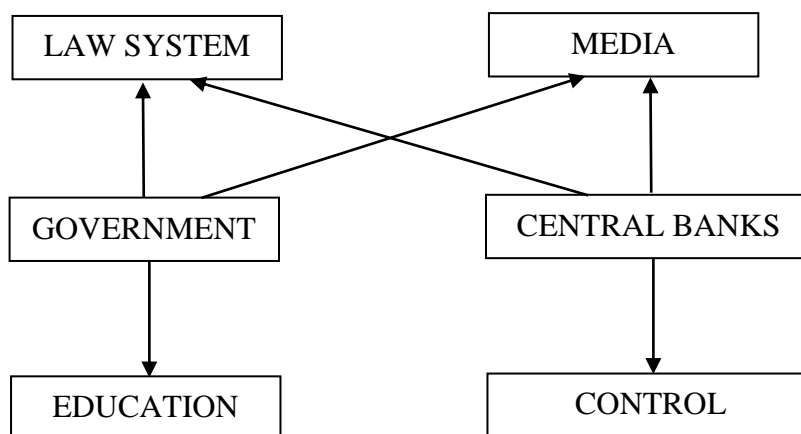

Fig. 1 - The co-operation, influence and negotiations among institution within one country. Source: own work.

The right side includes neutral or deposit operations on finance, which are not so problematic or which are even wanted – like planning for retirement or saving (to create some reserves for a not-so-good time).

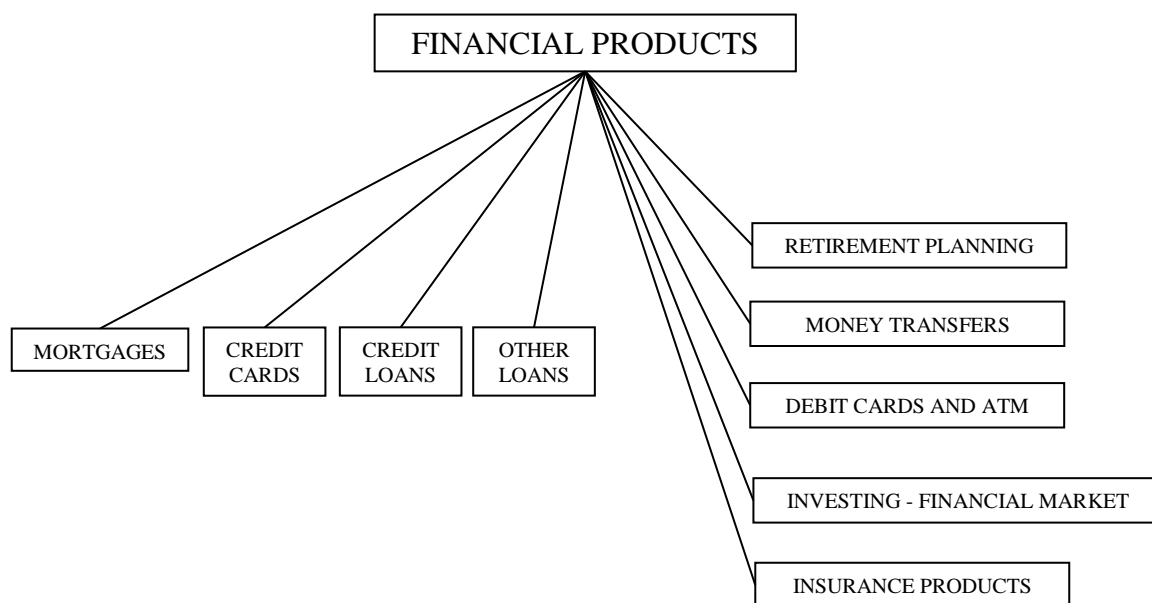

Fig. 2 - Financial products. Source: own work.

## **1.2 The situation in the Czech Republic**

There has been a lot of debate about the definition of financial literacy and many definitions are accepted.

The OECD (INFE) has defined financial literacy as follows: a combination of awareness, knowledge, skill, attitude and behaviour necessary to make sound financial decisions and ultimately achieve individual financial wellbeing.

The Czech Republic brings financial literacy into being in our lives in 2008 in the Standards (Ministry, 2007) of the Ministry of Education, Youth and Sports. There it is stated, that financial literacy is a set of knowledge, skills and behaviour of citizens needed to ensure the finances of the family and its active role in the financial market. One should be oriented in the problems connected with money, prices and be able to manage home households, including the managing of financial assets, and credits and loans with regard to changeable conditions. Financial literacy is composed of three components – currency, prices and the budget of the home.

Nowadays, the situation is changing everywhere. The financial crisis after 2008 and the following economic crisis led banks to decrease the price of money. People in our changing society wanted to reach the level of West-European countries as soon as possible in their lifestyles, and this situation led Czech citizens from their more conservative behaviour to the general belief that it is better to have loans, than to save money. This general idea was announced by lots of economic experts in the Czech media. In the beginning of 2015, the

level of deposit was nearly 1 billion of CZK by central Czech bank ([http://www.cnb.cz/cnb/STAT.ARADY\\_PKG.VYSTUP?p\\_period=1&p\\_sort=2&p\\_des=50&p\\_sestuid=1538&p\\_uka=1%2C2%2C3&p\\_strid=AAD&p\\_od=200511&p\\_do=201411&p\\_lang=EN&p\\_format=4&p\\_decsep=.](http://www.cnb.cz/cnb/STAT.ARADY_PKG.VYSTUP?p_period=1&p_sort=2&p_des=50&p_sestuid=1538&p_uka=1%2C2%2C3&p_strid=AAD&p_od=200511&p_do=201411&p_lang=EN&p_format=4&p_decsep=.)). In the comparison of the total cost of loans for Czech citizens - what is now about 2.6 billion of CZK. This result can be seen as good, because the biggest part of its mortgages and they are the best loan from the point of view of any financial specialist.

It looks like the economic and financial crisis meets the crisis of morality, but not only in financial markets. But the finance is topic of this paper. The current financial crisis has highlighted the need for financial education, education focused on practical life skills associated with administration of personal or family budgets, which are a prerequisite for the financial security of citizens and families. Various forms of investment and return on investment require a certain measure of determination and education. The willingness to take risks requires detailed mapping of the product to know before the signing of any agreement ways of calculation and estimation of possible difficulties. This situation creates the need to teach and educate a new generation by more sophisticated and practical methods. It is necessary to give lectures on practical topics, and their connection with practice, and not only on the theory about the function of something.

## **2 THE AIM AND METHODOLOGY**

Research conducted by author of the article was based on a questionnaire survey. In this article was investigated the state of the financial literacy in some countries of European Union. There was conducted a survey, in which 1062 participants answered to six questions aiming to discover their financial literacy. The questions included: the knowledge of one's own money balance, personal financial planning, knowledge of the relevant information, which describe a loan, financial product for the retirement, the knowledge of the availability of help, when one cannot pay his instalments and finally the purpose of a loan. Further, the survey gathered demographic data on the participants, age, gender, education and financial education.

The aim of this paper was to show the level of financial literacy in different countries and find, if there is any, some methods, differences or connecting matters, what can be used for the improvement of the situation, if needed.

Statistical method was used for its evaluation. The questionnaire contained some questions used by the Ministry of Finance of the Czech Republic, in very short versions. Furthermore, respondents were questioned on their information sources on managing money. "Knowledge" was assessed according to answers to questions.

Data were collected in 2014 at four different universities - in Ceske Budejovice, at University of Maribor, Uniwersytet Łódzki in Lodz and Aristotle University of Thessaloniki.

## **3 RESULTS**

The number of students participated in the questionnaire survey is showed in the next table 1. The total was 1062. Their age was from 18 to 50 years with the majority between 18 and 30.

Small number of students in higher age is caused by the system of education. There are two group of students in the samples, which participated – the majority of presenting studying, usually in the age about 20 and the small number of student is mature students. In this part are few students older, from 30 – 50 years.

Tab. 1 - Number of respondents in the survey. Source: own work.

Country	Number of students
The Czech Republic	486
Poland	250
Slovenia	253
Greece	73

There were from 21 to 38 % of men in the sample. In the level of education, the high school students were in the absolute majority – from 30 to 93 % depending on the country.

Their answers are showed in following tables.

Tab. 2 - Do you have knowledge about your financial situation, do you follow your bank balance? Source: own work.

Country	The Czech Republic	Poland	Slovenia	Greece
Yes, but not regularly – 1a	15.7 %	17.2 %	21 %	18 %
Yes, when needed – 1 b	29.4 %	39.6 %	41 %	29 %
Yes, regularly – 1c	54.5 %	42.8 %	37 %	47 %
No – 1d	0.4 %	0.4 %	1 %	7 %

Answers are acceptable if students are honest in their replies. The differences among countries are not big.

Tab. 3 - Do you plan your financial needs, incomes, outcomes, i.e. budget? Source: own work

Country	TheCzech Republic	Poland	Slovenia	Greece
Yes, but not regularly – 2a	58.2 %	24 %	No answer	7 %
Yes, when needed – 2b	5.9 %	42.4 %	No answer	30 %
Yes, every week – 2c	29.7 %	12.8 %	No answer	41 %
Yes, every month – 2d	3.5 %	9.2 %	No answer	15 %
Yes, every quarter – 2e	0.7 %	2 %	No answer	3 %
Other periodicity	1.7 %	0 %	No answer	0
No	0.3 %	9.6 %	No answer	4 %

Answers from this table are not so satisfactory, because the answers – when needed – are too close to the answer – no. There are lot of respondents, who do not plan their financial budget and too much students do not do it often or regularly.

Tab. 4 - Are you in possession of or thinking of a financial product which will support you in retirement? Source: own work.

Country	The Czech Republic	Poland	Slovenia	Greece
I have something prepared already – 4a	57.7 %	2 %	22 %	No answer yet
I am thinking about some product – 4b	22.7 %	34.9 %	33 %	No answer yet
I do not have any and do not think about it – 4c	19.6 %	63.1 %	45 %	No answer yet

These answers were a big surprise, because of the age of the majority of respondents. But there are big differences among countries involved in the research. Probably the good situation in the Czech Republic is arranged by parents of students.

Tab. 5 - Do you know who can help you if you are in the situation that you are not able to pay your instalment? Source: own work.

Country	The Czech Republic	Poland	Slovenia	Greece
Yes - 5a	82.9 %	65.9 %	59 %	67 %
No – 5b	17.1 %	34.1 %	41 %	33 %

More than half of students know what to do in the situation of debt. This situation is good because of the growing number of people fallen in debt.

From the next table, it follows that if the number in the previous table corresponds with number of students without financial education, then it is not caused by the educational system of schools.

Tab. 6 - Did you graduate in some financial studies? Source: own work.

Country	The Czech Republic	Poland	Slovenia	Greece
Yes	79.7 %	74.6 %	No answer	78 %
No	20.3 %	25.4 %	No answer	22 %

We can say that the number corresponds to „no knowledge“ from the previous table and it probably cannot be caused by not enough education.

The next two requests are oriented to loans and credits. The first one gives us a picture of what is so very important for students that they will buy it from money borrowed from the bank. Some respondents did not reply to this question. Probably it is too hard for them to imagine this situation or they do not want to think about it. The most often objects of their dream are cars and own houses. Lot of answers was oriented to the answer that is not a good aim, to have any credit, what is very positive answer for future.

The last request shows the situation in most preferred criteria for the choice of credit lines.

Nearly all students decided for costs of credit. It is nice. It is only a pity that they often do not know about the best comparison of costs (and the existence of this criterion) – APRC, which is an innovation in the law system of some countries (incl. the Czech Republic) and not so well known.

The next figure shows the results of Canonical Correspondence Analysis (CCA) made on the results of the sample of Czech respondents.

Fig. 1 - Ordination diagram of Canonical Correspondence Analysis (CCA) of Czech students (the other universities did not complete their search yet). Source: own work.

Empty points express those answers from the questionnaire about financial behaviour of respondents (see tables 2 – 5 for legend to labels). Points numbered 8a – 8c represent age of respondents (8a – up to 20 years, 8b – 21 to 30, 8c – 40 and more). The first axis shows 1.6 % of variability, the second axis shows 0.3 % of variability. The effect of age is significant ( $F = 2.7, p = 0.002$ ).

There is a gradient of financial literacy ranging from people with prevalingly right answers (2d – preparation of financial budget regularly, 4a – have financial product for safe pension, 1c – regular information about financial situation, 5a – knowledge about help in debt), to people with wrong answers (4c – no financial product for a safe pension, 2h – no budget, 5b – no knowledge about help in debt, 1d – no information about their financial situation). Only the age of respondents had a significant effect on the composition of answers ( $F = 2.7, p = 0.002$ ).

#### 4 CONCLUSION

In the current world of economic development, the issue of financial literacy is being discussed and scrutinised more frequently. It is undeniable that an increasing number of countries choose to deal with the financial literacy needs in their populations through the design and implementation of tailored, articulated and coordinated National Strategies for Financial Education.

This paper was focused on the level of financial literacy among the young and working Czech population between 18 and 50 years of age. This group of people was specifically chosen because of the importance of knowing the level of financial literacy of this generation, as it is the time of starting life, along with all of its difficulties, and out of which will arise the next

generation. The results can be used by the Ministry of Education, Youth and Sports as the basis for the evaluation of the level of financial education of this generation and for the possible adaptation of the Strategy. The results show that there follows an area of change in the educational process in the raising of young people, because not all are educated enough.

What is surprising is only in the difference in the time doing of a household budget and the answers of the very young and not so very young students (age difference). What matters more is education and care at home, and in the family, than at the school. Education, gender and even taking a financial course did not have a significant effect on respondents' behaviour in this survey.

It can be assumed that family experience and parental guidance are the most frequent sources of information on how to manage and handle finances. The correct model of financial behaviour, which includes discussion of a household budget and the preparation of financial strategies for a family by all its members, is very useful.

From preliminary results looks to be the financial literacy in Poland not good. A majority of Poles (62 %, by Stan wiedzy finansowej Polakow) assess their finance-related knowledge as very weak or weak, what correspond with the evaluation made at the university in Lodz – 58.8 % of their respondents see the situation as very poor. In Slovenia and Greece the level of financial literacy of students is relatively low, on average, when is compared with other students participating in PISA 2012 project. By journal Finance 2014 in Slovenia is average financial knowledge of a Slovene sufficient only for grade 2 from 5. Czech students in the majority refused to evaluate their level, but by lot of other searches (ING, ČNB and MFČR) is not the best.

In all countries is missing linkage between financial theory and its practical application in everyday life. The risk of over-indebtedness or falling into a spiral of debt as well as lack of awareness of the necessity of saving up for retirement were the other aspects strongly emphasized by respondents in all countries. There is space for the building of better educational financial system in all participated countries.

The main goal of this paper is the co-operation of lecturers from different universities and countries and the possibility to exchange information in the following research and help.

## **ARE THE BANKRUPTCY PREDICTORS SPECIFIC FOR A GIVEN TIME OR BRANCH? THE EVIDENCE FROM THE CZECH MANUFACTURING AND CONSTRUCTION COMPANIES**

*Michal Karas, Mária Režňáková*

### **Abstract**

Bankruptcy is still an up to date topic, as still many companies go bankrupt. Many scientific efforts have been dedicated to creating a more accurate model by to analyzing different sets of predictors (variables of the model) or a different set of methods. Previous work showed that these models are less effective in application in alternative branch or time.

In this paper we test a smof several ratios used in bankruptcy prediction models on a large sample of Czech companies from two branches – manufacturing and construction. We found that the predictor's significance varies considerably between the analyzed branches. In other word we found that some predictors are specific for a given branch. In addition, we found only one predictor significant in both branches for a given moments prior bankruptcy.

The results suggest that a different or modified set of predictors should be used for predicting bankruptcy in alternative branch.

*Keywords: bankruptcy prediction models, financial ratios, model robustness, manufacturing, construction*

JEL Classification: G33, C51

### **1 INTRODUCTION**

The neo-classical economic theory postulates that bankruptcy permits the company to free its poorly used economic resources and deploy them more effectively (see Lízal, Schwarz, 2012). In the short term though, this translates into large economic losses for investors and other stakeholders, as well as significant social and economic costs (Shuai, Li, 2005). For Smrčka, Strouhal, Schönfeld (2012), the societal costs of bankruptcy are mainly higher unemployment, loss of workers' qualifications, greater burden on the country's social system, and dissipation of the company-specific know-how.

By Wu (2010), the internal enterprise causes of bankruptcy may be seen in insufficient management skills, marketing, and inability to compete. They are reflected in the company performance as recorded in the books. For this reason, accounting data or rather financial ratios are a frequent source of information for assessing the stability and viability of an enterprise.

The scientific efforts of predicting corporate bankruptcy based on the analysis of financial ratios dated back to 1960's. Beaver (1966) and Altman (1968) were among the first authors who had the idea of predicting bankruptcy only from financial indicators. They found that the signs of bankruptcy can be traced back for five years. Using a discrimination analysis, Altman (1968) created the first bankruptcy model. According to many authors Altman's model still represents an effective tool to predict bankruptcy (see Li, Ragozar, 2012, Satish, Janakiram, 2011, El Khoury, Al Beaño, 2014, Alkhatib, Al Bzour, 2011). To establish its parameters, Altman compared the data on active companies with the data on bankrupt companies. This data reflected the status as it was one year before the bankruptcy. For variables, Altman chose 5 of the 26 possible financial indicators, the combination of which showed the best

discriminatory capability. This technique is known as creating a reduced-form model, and it is presently the most frequent approach to modeling. It was used, for example, in the studies conducted by Lin Liang, Chen (2011); Wang, Lee (2008); Niemann, Schmidt, Neukirchen (2008); Tseng, Hu (2010); Psillaki, Tsolas, Margaritis (2009); and Cheng, Chen, Fu (2006). Overview of existing models could be found in Čámská (2013). The research on bankruptcy prediction could be divided into two lines:

**1) Testing various methods that can improve the prediction accuracy of models.**

Historically, various algorithms have been employed to devise models of bankruptcy. The first was the linear discrimination analysis (LDA) method (Altman, 1968), developed by Fisher (1936). In reaction to its shortcomings, other algorithms were applied. A number of parametric methods exist, such as the probit model (Zmijewski, 1984) the logistic regression or logit model (Martin, 1977; Ohlson, 1980) and the Cox model (Henerby, 1996; Shumway, 2001). Over time, nonparametric methods were also tried, such as artificial neural networks (ANN) (Al-Shayea, El-Refae, 2012, Back, Laitinen, Sere, 1996; Kim, Kang, 2010, Cút, 2014), Data Envelopment Analysis (DEA) methods (Cielen, Peeters, Vanhoof, 2004; Ding, Song, Zen, 2008), and even some combinations of parametric and non-parametric methods (Andres, Lorca, De Cos Juez, Sanchez-Lasheras, 2011; Chen, Hsiao, 2008). Nevertheless, the LDA method remains the most widely used classification algorithm (Aziz, Dar, 2006). One of the reasons may be the prevalent opinion that the choice of classification method does not offer much potential to improve the bankruptcy model (Niemann, Schmidt, Neukirchen, 2008), i.e. that there is not a statistically significant difference in accuracy between the individual methods (Aziz, Dar, 2006). When speaking about the methods that can be used, one should be aware that there is a trade-off between method accuracy and the interpretability of its outcomes (see James et al., 2013). The advantage of models based on LDA is that outcomes are ease to interpret. This is possibly why the LDA method still remains the most widely used method (see Aziz, Dar, 2006) and why previous models based on LDA (such as Altman's) are still widely used and discussed.

**2) Identifying suitable variables of a model (so called predictors).** The literature (Chen, Hsiao, 2008) categorizes the companies undergoing business crises as follows:

- Companies lacking capital to manage the business and starting to have problems meeting their short-term monetary obligations (Deakin, 1972; Gilson, 1989). Financially, this condition is detectable in the values of current liquidity, quick liquidity, accounts receivable, cash flow, total asset turnover, and other factors.
- Companies with a negative value of non-distributed profit for two consecutive periods or a negative growth for at least 1 year. The signs of financial problems appear in the following indicators (Altman, 1983): asset profitability, sales receipts, profits before and after taxes, and operating profit margin.
- Companies whose shares on a public stock market show an overall drop, are excluded from trading, or withdrawn from the market.

A timely recognition of signs pointing to potential bankruptcy provides a chance to avert it. That is why the economic research has been on a long quest for indicators that could signal the threat of bankruptcy at the earliest possible time. In devising a model, it is rather difficult to collect sufficient data on bankrupt companies, as bankruptcy is relatively rare in business. The first models (Altman, 1968; Ohlson, 1980; Zmijewski, 1984, and others) were designed on the basis of financial ratios calculated using company data one year prior bankruptcy (t+1 period). One of the methods of increasing the accuracy of a model is to use indicators covering several years before bankruptcy (e.g. Perry et al., 1984). The models so designed

included only those indicators (predictors) whose bankruptcy-predicting ability had been established for a single interval only, specifically one year before the bankruptcy. Deakin (1972) found that the ranking of predictor significance changes with the receding time. Deakin's conclusion was confirmed by the work of Grice and Dugan (2001). Shumway (2001) criticizes the earlier bankruptcy models (of Altman, Zmijewski and Ohlson) as static since the time factor is ignored. These issue were also considered by Henerby (1996) who, aided by the Cox's model (see Cox, 1972), analyzed the appropriateness of cash flow-based indicators for predicting bankruptcy, and concluded that these indicators are statistically most significant 3 years before the event and can therefore serve as early indicators. Lin, Liang, Chen (2011) summarize this problem in following way: *“Early studies tend to treat financial ratios measuring profitability, liquidity and solvency as significant indicators for the detection of financial difficulties. However, reliance on these financial ratios can be problematic. The order of their importance, for example, remains unclear as different studies suggest different ratios as the major indicators of potential financial problems.”*

From a different point of view authors such as Platt and Platt (1990), Grice and Dugan (2001), Niemann et al (2008) and Wu, Gaunt and Gray (2010), have pointed out this problem and indicated that the predication accuracy of bankruptcy models (their ability to differentiate correctly between a company threatened by bankruptcy and a prospering company) falls markedly when they are applied to a different branch, period or economic environment than original environment.

Such arguments motivate efforts aimed at creating new bankruptcy prediction models. In this context, Thomas Ng, Wong and Zhang (2011) point out the need of creating models for branches such as construction, as the existing models are inappropriate for this branch. In general, Kaplinski (2008) claims that bankruptcy prediction models should be adjusted to the economic conditions of the given country or even branch.

The possible explanation could be that the significance of bankruptcy predictors is not stable over time or these predictors are specific for given time, place and branch.

The aim of this paper is to analyze the significance of a set of financial ratios in different time periods and two branches. Moreover to answer the question whether is possible to find such predictors that are not specific for given time period or branch. The financial ratios, in this research, were analyze on a univariate base, as this is a starting point of search for a more robust bankruptcy models, next step will be performing the analysis on multivariate base.

## 2 SAMPLE AND METHODS

The sample under investigation is comprised of 34,533 companies in two branches in Czech Republic, namely, Manufacturing and Construction. There are 34,229 active (or financially healthy companies) and 304 bankrupt companies (a year before bankruptcy), for more details see following table.

Tab. 1 – Numbers of investigated companies. Source: Our own analysis of data from the Amadeus database

<b>Branch</b>	<b>Active</b>	<b>%</b>	<b>Bankrupt</b>	<b>%</b>	<b>Total</b>	<b>%</b>
M – Manufacturing	27748	80,35	161	0,47	27909	80,82
C– Construction	6481	18,77	143	0,41	6624	19,18
<b>Total</b>	<b>34229</b>	99,12	<b>304</b>	0,88	<b>34533</b>	100,00

Taking into consideration, that bankruptcy of a company is a rare phenomenon, the branches with a relatively high number of bankrupt companies were chosen for the purpose of the research. Even though the proportion of bankrupt companies in the sample is relatively low, only 0,88%.

The data were obtained from AMADEUS (Analysis Major Database for European Sources). The bankrupt companies in our sample declare bankruptcy during years 2008 and 2013, although data on these companies was monitored over 5 time intervals. In the case of the bankrupt companies, the first interval studied is the year before bankruptcy, which is referred to as period  $t+1$ . The period studied is then the period between the years 2003 and 2013.

As there is insufficient number of observation of bankrupt companies in the branch of Transportation and storage, this data were not further analyzed.

We test a set of 17 financial ratios covering several aspects of company's financial health. These ratios are often used in studies on bankruptcy prediction problems (see Beaver, 1966; Altman, 1968, Karas, Režňáková, 2013, Čámská, 2013, Cút, 2014)

Tab. 2 – Numbers of investigated ratios. Source: Beaver (1966), Altman (1968), Karas, Režňáková (2013), Čámská (2012, 2013)

No.	Ratio	Shortcut
1.	Current ratio	CR
2.	Working capital/total assets	WC/TA
3.	Working capital/sales	WC/S
4.	EBIT/total assets	EBIT/TA
5.	EBITDA/total assets	EBITDA/TA
6.	EAT/equity	ROE
7.	Current liabilities/total assets	CL/TA
8.	Long-term liabilities/total assets	LTL/TA
9.	Debt-equity ratio	DER
10.	Sales/total assets	S/TA
11.	Sales/Stock	S/St.
12.	Sales/Debtors	S/Deb.
13.	Sales/Current liabilities	S/CL
14.	EBIT/Interest	EBIT/Int.
15.	EBITDA/Interest	EBITDA/Int.
16.	Fixed assets/total assets	FA/TA
17.	Sales/Operating revenue	S/OR

For identifying potential predictors we used a two sample t-test with equal or rather unequal variances. The test procedure can be described in following way.

Let there be two independent random samples ( $X_1, \dots, X_n$ ) from distribution  $N(\mu_1; \sigma^2)$  respectively ( $Y_1, \dots, Y_m$ ) from distribution  $N(\mu_2; \sigma^2)$ . We assume that  $n \geq 2; m \geq 2; \sigma^2 > 0$ .

The t-test tests a null hypothesis, that the difference between the means of both groups ( $\mu_1, \mu_2$ ) is equal to some constant ( $\Delta$ ), in most cases to zero ( $\Delta=0$ ), i.e:

$$H_0 : \mu_1 - \mu_2 = \Delta \quad (1)$$

Against the alternative hypothesis

$$H_1 : \mu_1 - \mu_2 \neq \Delta \quad (2)$$

The test criterion, under assumption of **equal** variances can be written in following form:

$$|T| = \left| \frac{\bar{X} - \bar{Y} - \Delta}{\sqrt{(n-1) \cdot S_x^2 + (m-1) \cdot S_y^2}} \cdot \sqrt{\frac{nm \cdot (n+m-2)}{n+m}} \right| \geq t_{n+m-2}(\alpha) \quad (3)$$

where

$\bar{X}, \bar{Y}, S_x^2, S_y^2$  are characteristics of the two random samples.

The test criterion, under assumption of **unequal** variances can be written in following form:

$$\frac{|\bar{X} - \bar{Y}|}{S} \geq \frac{v_x t_{n-1}(\alpha) + v_y t_{m-1}(\alpha)}{v_x + v_y} \quad (4)$$

where

$$S_x = \frac{1}{n-1} \left( \sum_{i=1}^n X_i^2 - n\bar{X}^2 \right), S_y = \frac{1}{m-1} \left( \sum_{i=1}^m Y_i^2 - m\bar{Y}^2 \right) \quad (5), (6)$$

$$S = \sqrt{\frac{S_x^2}{n} + \frac{S_y^2}{m}}, v_x = \frac{S_x^2}{n}, v_y = \frac{S_y^2}{m} \quad (7), (8), (9)$$

Financial ratios were defined for each analyzed company in the sample of active and in the sample of bankrupt companies. The ratios were calculated according to status of the company (i.e. active or bankrupt), the last reported year (2008, 2009, ..., 2013), i.e. in case of bankrupt companies the year of bankruptcy and finally according to the number of years prior bankruptcy (t+1, t+2, ..., t+5).

The F-test and t-test were applied to test the potential differences between the samples of active and bankrupt companies ratios and the p-values of these tests were analysed.

### 3 RESULTS

The following table shows a descriptive statistics of the first analyzed ratio, the current ratio (CR) based on the 2013 year results. The following designation for branch or rather the status: C – Construction and M – Manufacturing. Active companies are denoted with (A), bankrupt ones with (B).

For examples CR M (A) is the indicator of current ratio calculated for active companies from the branch of manufacturing. All ratios are calculated at moment t+1.

Tab. 3 – Descriptive statistics of the current ratio indicator Source: Our own analysis of data from the Amadeus database

<b>Ratio</b>	<b>Mean</b>	<b>Median</b>	<b>Std. Dev.</b>	<b>Quant. (1%)</b>	<b>Quant. (99%)</b>
CR C (A)	11,28752	1,48375	195,3601	-0,06849	146,5467
CR C (B)	17,91368	1,085861	50,46679	-44,62	196,1683
CR M (A)	11,28752	1,48375	195,3601	-0,06849	146,5467
CR M (B)	17,91368	1,085861	50,46679	-44,62	196,1683

The following steps were taken to identify potential predictors respectively to identify those predictors that are or are not specific for given industry or time.

- 1) To identify the predictors that are significant at 5% level of t-test for each of the analysed branches, **regardless the number of years prior the bankruptcy and the last year**.
- 2) To divide the set of predictors from point 1 into the set of predictors that are specific for a given **time** (i.e. they are significant in only at one moment prior bankruptcy) and on a set of predictors that are significant in more than moment prior bankruptcy (t+1, t+2,..., t+5).
- 3) To divide the set of predictors from point 1 into the set of predictors that are specific for a given **branch** (i.e. they are significant in only one branch) and on the set of predictors that are significant in more than one **branch** (2, 3 or 4).

The following table shows the summary of results of t-test and F-test for the indicator of current ratio (CR) for companies that bankrupt in 2013 (i.e. 2013 is theirs last year). The ratios were tested separately for every year prior bankruptcy (t+1, t+2,...t+5). For example CR C1 is the current ratio calculated using the data on construction companies one year prior bankruptcy.

The statistical significance of the t-test results was highlighted by using the following designation: \*statistically significant at the 10 % level, \*\*statistically significant at the 5 % level, \*\*\* statistically significant at the 1 % level.

When analysing only the year 2013 as the last year, we found that the current ratio is a statistically significant predictor in five observations. In the branch of construction, the mentioned ratio is significant at 5% level in the moment t+2 and at 10% level even in the moment t+3 or t+4.

Furthermore, there are two significant observation of the mentioned ratio in the branch of manufacturing, namely at 5 % level in moment t+2 and at 10% level even in moment t+4.

When analysing the whole period (not only 2013), we found that only 38% (i.e. 65 of 170) of analyzed ratios are significant bankruptcy predictors at least at one moment prior bankruptcy (t+1, ... , t+5) regardless the last year. The next table show which predictors are significant in which moment prior bankruptcy for analyzed branch.

The following tables show the results of t-test (in form of p-value) of all analyzed predictors. The p-values lower than 5% are highlighted.

As the tested predictors were significant in several analyzed years (2008-2013), the table shows only the lowest p-values (i.e. the most significant value) achieved by the given predictor in the analyzed period.

## 4 DISCUSSION

The accuracy of bankruptcy prediction models is determined by the effectiveness of its predictors. Studies as Platt and Platt (1990), Grice and Dugan (2001), Niemann et al (2008) and Wu, Gaunt and Gray (2010) have pointed out that the predication accuracy of bankruptcy models falls markedly when they are applied to a different branch, period or economic environment than that from which the data on which they were developed was taken often. These studies often present this problem on the example of Altman's model (see Altman, 1968, 1983). Three of here the analysed predictors were included in Altman's model too, i.e. the relative size of working capital (WC/TA) measuring liquidity, the return of assets (EBIT/TA) measuring profitability and the total assets turnover (S/TA) measuring the intensity of assets use. It is worth to mention that Altman's model was designed for manufacturing companies. We found that the WC/TA, EBIT/TA and CL/TA are time specific in the branch of manufacturing. The S/TA ratio works well in manufacturing and construction. In our previous research, although by using different approach, we found that the total assets turnover (S/TA) represents a very significant ratio in predicting corporate bankruptcy (see Karas, Režňáková, 2013).

From the table 5 is it obvious, that the analyzed set of predictors is more effective in the branch of manufacturing. The potential explanation could be that most of the previous studies were focused on the manufacturing companies.

But on the other hand 5 of 17 predictors are **specific for a single moment prior bankruptcy in one of the branches**. These predictors are, in the branch of manufacturing, the relative size of net working capital (WC/TA), the return on assets (EBIT/TA) and the short-term indebtedness (CL/TA). And in the construction branch, such predictor is represented by return on equity (ROE) and the debt-equity ratio (DER).

While the first two mentioned ratios (i.e. WC/TA and EBIT/TA) are often used in bankruptcy prediction models, especially those by Altman (see Altman, 1968, 1983). The return on assets ratio (EBIT/TA) is additionally specific for the branch of manufacturing.

Most of the predictors **are not specific for a single moment prior bankruptcy, i.e. they are significant in more periods prior bankruptcy**. Even predictors significant in all five year prior bankruptcy could be found. Such predictors are, in **manufacturing** branch, the total assets turnover (S/TA), stock turnover (S/St.), the current liabilities turnover (S/CL.), the proportion of tangible assets (FA/TA), the ratio of sales and operating revenue (S/OR) and the interest cover calculated by using EBIT or EBITDA, (EBIT/Int. or EBITDA/Int.), see details table 5. Furthermore, same set of ratios, with the exception of total assets turnover (S/TA) is also significant five year prior bankruptcy in the **construction** branch.

Remarkable is the finding that the return on assets calculated using EBIT (i.e. EBIT/TA) and the short-term indebtedness (i.e. CL/TA) are not a significant predictors in the **construction** branch. What is more, the long term indebtedness (LTL/TA) does not represent a significant predictor in **any of the analyzed branches in any analyzed moment prior bankruptcy**.

## 5 CONCLUSION

According to Perry et al., (1984) one of the methods of increasing the accuracy of a bankruptcy prediction models is to use indicators covering several years before bankruptcy. In this research we analyze the significant of bankruptcy predictors in the context of the branch and time prior bankruptcy. We found there ratios that represents a significant bankruptcy predictor in just one branch, i.e. they are specific for this branch. Moreover, we found that only 8 of 17 analyzed predictors were significant in all of the analyzed five year prior bankruptcy, 8 of them in the branch of manufacturing (i.e. EBITDA/TA, S/TA, S/St., EBIT/Int., EBITDA/Int., FA/TA, S/OR and S/CL.), same set (with exception of S/TA) is also significant in the construction branch. As same predictor are time specific, or even not significant at all, this lead us to conclusion, that **only some** predictors could be used as early warning indicators or used to predict bankruptcy more years ahead.

As the branch specific ratios are often incorporated in bankruptcy models, they can be a cause of model's lower accuracy in application in different field.

## **BANKS FROM THE SOCIETE GENERALE GROUP AND THEIR SENSITIVITY TO THE BANK RUN**

*Pavla Klepková Vodová*

### **Abstract**

The aim of this paper is to measure the sensitivity of commercial banks from the Societe Generale Group to the bank run and to compare their sensitivity with average sensitivity of banks in particular countries. We have used the methodology of scenario analysis for the liquid asset ratio. During first years of the analyzed period, almost all banks would be able to face the bank run. However, only depositors of three banks would be able to withdraw 20% of their funds during and after the financial crisis. The group of the most vulnerable banks consists from SKB Banka from Slovenia, Euro Bank from Poland and Banka Societe Generale Albania. Banks from the Societe Generale Group are mostly more sensitive to the bank run than corresponding banking sectors. Except of three banks in 2004, all subsidiary banks are more sensitive to the bank run than the parent bank.

*Keywords: liquid asset ratio, scenario analysis, bank run, Societe Generale Group, financial conglomerate*

JEL Classification: G21, G32, G01

### **1 INTRODUCTION**

The emergence of financial conglomerates is one of the major trends in the financial sector in recent years. There are many motives for conglomeration; however, it should not be omitted that financial conglomerates are very often linked also with higher risks. As liquidity problems of some banks during global financial crisis re-emphasized, liquidity is very important for functioning of financial markets and the banking sector. From the variety of risks of banking business, we will therefore focus on liquidity risk. The insufficient liquidity of a bank may lead to a situation when the majority of depositors intend to withdraw their funds which will cause a bank run. Even if such situation may be perceived as exceptional, extreme or simply unexpected, it is still a plausible event, therefore in accordance with the recommendation of the Basle Committee for Banking Supervision financial institutions should gauge their potential vulnerability to such events by conducting of stress tests (BIS, 2000).

We will therefore use the methodology of sensitivity analysis which will enable us to address this issue. With banks in eleven countries of the Central and Eastern Europe (CEE countries), Societe Generale Group belongs to the largest financial conglomerates in this geographic area. The aim of this paper is to measure the sensitivity of commercial banks from the Societe Generale Group to the bank run and to compare their sensitivity with average sensitivity of banks in particular countries.

The paper is structured as follows. Next section gives theoretical background of liquidity risk and bank runs. Then we focus on methodology, data and results of scenario analysis. Last section captures concluding remarks.

## **2 THEORETICAL BACKGROUND**

Liquidity risk and the phenomenon of bank runs are intensively interconnected because the insufficient liquidity of a bank may lead to a bank run.

Bank for International Settlements (BIS, 2008) defines liquidity as the ability of bank to fund increases in assets and meet obligations as they come due, without incurring unacceptable losses.

According to Nikolau (2009), the term liquidity risk includes central bank liquidity risk, funding liquidity risk, and market liquidity risk. Central bank liquidity risk is a risk that a central bank would not be able to supply the liquidity needed to the financial system. This risk is highly unlikely because a central bank can only be illiquid to the extent that there is no demand for domestic currency, e.g. in case of hyperinflation or an exchange rate crisis. Funding liquidity risk is the risk that the bank would not be able to efficiently meet both expected and unexpected current and future cash flow and collateral needs without affecting either daily operation or the financial condition of the bank (BIS, 2006). It is the risk that over a specific horizon the bank will become unable to settle obligations with immediacy. Market liquidity risk is the risk that a bank cannot easily offset or eliminate a position at the market price because of inadequate market depth or market disruption (BIS, 2006).

Liquidity risk arises from the stochastic nature of the bank liquidity: although the bank can be liquid at any given time, there may be quite unpredictable situations such as unexpected utilization of credit lines, unforeseen deposit withdrawals, untimely loan redemption, a liquidity need resulting from asset price developments or failed or delayed payments by sellers of credit risk protection which can threaten bank liquidity (ECB, 2002).

Unforeseen deposit withdrawals, mentioned in the previous definition, may be a result of bank run. Banks have been always plagued by the problem of bank runs. Freixas and Rochet (1997) define bank run as a situation when depositors observe large withdrawals from their bank, they fear bankruptcy and respond by withdrawing their own deposits. Withdrawals in excess of the current expected demand for liquidity generate a negative externality for the bank experiencing the liquidity shortage, since they imply an increase in the bank's probability of failure. Banks are vulnerable to runs that can lead to closure and liquidation because they issue liquid liabilities in the form of deposit contracts, but invest in illiquid assets in the form of loans. A banking panic then occurs when depositors at many or all of the banks in a region or a country attempt to withdraw their funds simultaneously (Allen & Gale, 1998). Bank run is very dangerous even for healthy banks.

The theoretical literature on bank runs is based mostly on the study of Bryant (1980) and the model of Diamond and Dybvig (1983). Both papers accentuate that bank runs are self-fulfilling prophecies. Many authors build on these two papers. Among the newest papers, we can mention e.g. Brown et al. (2014), Gertler and Kiyotaki (2013), Goedde-Menke et al. (2014) or Wang and Lin (2014).

As bank runs are typically perceived as costly and negative for the banking sector and the whole economy, most economists, regulators in particular, try to seek the best way how to prevent bank runs. One of the possibilities is to establish a functional deposit insurance scheme. In spite of the fact that in most European countries, deposit insurance covers nowadays 100% of the deposit amount up to the limit EUR 100,000, it may be useful to measure the sensitivity of banks to bank run (as it still remains to be a plausible event).

### **3 METHODOLOGY AND DATA**

Scenario analysis is one of the possible tools how to assess the vulnerability of banks to the bank run (for other possibilities, see e.g. Teplý et al, 2012). Therefore we will describe scenario analysis based on selected liquidity ratio in the first part of this section, and then we will focus on data used.

#### **3.1 Liquid asset ratio**

Liquidity ratios are used for liquidity risk measurement and it is a stock-based approach which can help to identify main liquidity trends (Vodová, 2013a). The liquid asset ratio belongs to the most commonly used liquidity ratios. Equation 1 shows the principle of its calculation.

$$LIA = \frac{\text{liquid assets}}{\text{total assets}} * 100(\%) \quad (1)$$

The liquid asset ratio (LIA), i.e. the share of liquid assets in total assets, should give us information about the general liquidity shock absorption capacity of a bank. It shows which part of the total assets can be readily converted to cash. As a general rule, the higher the value of this ratio, the higher the capacity to absorb liquidity shock, given that market liquidity is the same for all banks in the sample. Nevertheless, high value of this ratio may be also interpreted as inefficiency since liquid assets yield lower income liquidity bears high opportunity costs for the bank. Therefore it is necessary to optimize the relation among liquidity, profitability and efficiency (see e.g. Řepková, 2014, or Řepková, 2013).

As we use the BankScope measure of liquid assets, the term “liquid assets” includes cash, government bonds, short-term claims on other banks (including certificates of deposit), and where appropriate the trading portfolio. BankScope harmonizes data from different jurisdictions to arrive at a globally comparable indicator. This is particularly advantageous in this case when we compare banks from different countries.

#### **3.2 Scenario analysis based on liquid asset ratio**

Stress testing plays a complementary role in risk management practices of banks. Liquidity stress test should identify and quantify the potential lack of liquidity for specific stress scenario and determine the way how to close this lack at predefined costs. Three types of stress scenarios are usually applied: idiosyncratic, market, and combination of both. The idiosyncratic scenario typically represents a simulation of an outflow of deposits or a decline in the rating of the bank. The market shock usually assumes the decline in the value of certain assets or disturbances in the money or credit markets. These two scenarios are accompanied by other macroeconomic shocks, such as the decline in economic activity, growth of loans in default or deterioration of the sovereign rating (Komárková et al., 2012).

Several central banks and other supervisory authorities have applied stress tests of liquidity, e.g. in Netherland (Van den End, 2008), in the Czech Republic (Komárková et al., 2011) or in Romania (Negrila, 2010). However, their tests are not possible to repeat with publicly available information. Therefore we will focus also on other less complex studies which measured the impact of bank run on bank liquidity on selected liquidity ratios. Komárková et al. (2011) simulated the deposit withdrawals on average to 11% of total deposits. Negrila tested the impact of sudden drawing of 20% from deposits of individuals and 10% from deposits of corporate clients. Boss et al. (2004) stressed liquidity ratios by the scenario in which nonbank customers withdraw 20% of their deposits; they continued their scenario

analysis by the test of impact of withdrawal of 50% of nonbank deposits (Boss et al., 2007). Jurča and Rychtárik (2006) considered the scenario of decline in clients' deposits by 20%. Rychtárik (2009) measured the sensitivity of Luxembourg banks to withdrawal of 20% of clients' deposits.

Based on these studies and on available data, we will simulate a run on a bank by the withdrawal of a certain volume of clients' deposits. We simulate a 20% withdrawal of deposits; this haircut is applied on the total deposits not taking into account agreed maturities of different types of deposits. This is the way how to model an outflow of primary sources from the bank. To calculate the stressed value of the liquid asset ratio, we have to deduct the volume of withdrawn deposits, i.e. 20% of clients' deposits, from liquid assets. Bank must use liquid assets to be able to repay deposits. At the same time, volume of total assets is also decreasing as a result of this operation. Equation 2 captures these modifications.

$$LIA_S = \frac{\text{liquid assets} - 0.2 \cdot \text{deposits}}{\text{total assets} - 0.2 \cdot \text{deposits}} \cdot 100(\%) \quad (2)$$

$$\Delta LIA = \frac{LIA_S - LIA_B}{LIA_B} \cdot 100(\%) \quad (3)$$

As a next step, we will compare this stress value of the liquid asset ratio ( $LIA_S$ ) to the baseline value of this ratio ( $LIA_B$ , i.e.  $LIA$ ). The percentage change will be calculated according to the Equation 3. The results will show the magnitude of the relative changes between the stress and baseline values which will enable us to find out which bank is the most vulnerable, if banks from the Societe Generale Group are more or less sensitive to bank run than it is typical for banks in particular countries and if the parent bank is more or less sensitive to the bank run than subsidiary banks.

### **3.3 Data used**

With a presence in 76 countries, more than 148,000 employees and 32 million individual customers, Societe Generale is one of the leading financial services groups. Measured by the sum of total assets, the parent company Societe Generale is the third biggest bank in France and the eightens biggest bank in the world (Tab. 1). Societe Generale (hereinafter also SG) is a universal bank which split its businesses into three main divisions: Retail banking in France, International retail banking, financial services and insurance and Corporate and investment banking, private banking, asset management and securities services.

Focusing on the group of CEE countries, eleven banks from eleven countries belong to the Societe Generale Group. Tab. 1 provides more details about these banks which are included in our sample. Although globally they cannot be seen as very large banks (as we can see from its worldwide rank), these banks belong mostly to leading banking institutions in the region of CEE countries.

We used unconsolidated balance sheet data, mostly over the period from 2004 to 2013 (with the only exception of Euro Bank), which were obtained from the BankScope database (data for Euro Bank for 2004 were missing).

Tab. 1 – Information about banks in the sample. Source: Author’s processing.

## 4 RESULTS AND DISCUSSION

The first part of this section shows the baseline values of the liquid asset ratio. The second part of this section focuses on the stress values of the liquid asset ratio. The last part of this section analyzes the severity of the stress scenario.

### 4.1 Baseline values of liquid asset ratio

The baseline values of liquid asset ratio (Equation 1) for all banks and all countries (average values for individual banking sectors) are presented in Appendix 1. Fig. 1 shows the value of the liquid asset ratio for parent bank. Median values of liquid asset ratio for individual banks from the Societe Generale Group and median values for corresponding countries (banking sectors) are included for comparison.

Fig. 1 – Baseline values of liquid asset ratio. Source: Author’s calculation.

As higher values of the liquid asset ratio means higher liquidity, it is evident that, with the only exception of the year 2004, the liquidity of parent bank is higher than liquidity of its subsidiary banks. Moreover, the gap between these two values is increasing in recent years. Focusing on individual banks from the group (see Appendix 1), Euro Bank, CB Mobiasbanca and SKB Banka are less liquid for the whole analyzed period; SG Expressbank and SG - Splitska banka for the period 2005-2013; and SG Banka Montenegro for the period 2006-2013. It is evident, that beginning in 2007, the majority of banks belonging to the Societe Generale Group became less liquid than the parent bank.

If we compare the values of liquid asset ratio of subsidiary banks with average values in corresponding banking sector, we get very similar results. In most cases, liquidity of banks belonging to the Societe Generale Group is below average of the banking sector. The only exception is BRD - Group Societe Generale from Romania for the whole analyzed period. Exceptions are also banks from Albany, the Czech Republic, Macedonia and Serbia, but only for the first part of the analyzed period.

The decreasing liquidity of most banks in the sample, and the fact that their liquidity is much lower than in corresponding banking sectors, may suggest that maybe we should take into account also the possibility of intra-group support. The probability that at least some subsidiary banks could provide some liquidity support to the parent company can be also confirmed by the survey of Bank for International Settlements. According to findings of this survey (BIS, 2012), financial groups which encountered problems between 2007 and 2009 during the financial crisis typically had to consider the question of intra-group support. The level of intra-group support and interconnectedness of legal entities within the group affects the extent to which the failure of one entity poses contagion risk for other entities within the group. Intra-group liquidity support consists of various types of support measures, such as (a) a credit or a credit line provided by one entity to another entity within the group; (b) intra-group cross shareholdings; (c) trading operations whereby one group entity deals with or on behalf of another group entity; (d) central management of short-term liquidity within the group and (g) guarantees and commitments provided to or received from other companies in the group. Support measures may exist in two forms: upstream support (support provided by a subsidiary to its parent) and downstream support (support provided by a parent to its subsidiary). Both types of support typically increase the risk of loss to the provider and adversely affect its solvency, liquidity and profitability. Values of liquid asset ratio of parent bank and its subsidiaries indicate the higher probability of upstream support.

As values of liquid asset ratio are quite low in some cases, it is useful to measure the vulnerability of banks to possible bank run with the use of scenario analysis.

#### **4.2 Stress values of liquid asset ratio**

We have calculated stress value of the liquid asset ratio for parent bank, subsidiaries and corresponding banking sectors. Detailed values are provided in Appendix 2, value for parent bank and median values for subsidiaries and banking sectors (countries) are presented in Fig. 2.

As we can see, although the values are lower, the development trend is logically the same as in case of baseline values of liquid asset ratio. Liquidity of parent bank after the withdrawal of 20% of client's deposits is the highest, followed by liquidity of individual banking sectors (countries). Subsidiary banks are the less liquid. As the median value of the stress liquid asset ratio is negative in 2010 and 2012, it is obvious that some banks would not be able to finance such deposit withdrawals. During first years of the analyzed period, with the only exception of Euro Bank in 2005, all banks would be able to face the bank run. However, the situation

has completely changed during the financial crisis. Only depositors of SG - Splitska banka, Komerčni banka, CB Mobiasbanca and BRD – Group Societe Generale would be able to withdraw 20% of their funds in the whole period 2008-2013. Other banks would not have enough liquidity to meet their requirements, at least in some years, which is proved by negative LIA<sub>s</sub> value (Appendix 2).

Fig. 2 – Stress values of liquid asset ratio. Source: Author’s calculation.

### 4.3 Severity of the stress scenario

It is useful to calculate also the percentage decreases of the liquid asset ratio caused by the scenario “Bank run”. Results of Equation 3 are presented in Tab. 2 (median values for banks and individual countries) and in Appendix 3 (more detailed results). The decrease of LIA can inform us: (i) which bank (and which banking sector) is the most vulnerable, (ii) if banks from the Societe Generale Group are more or less sensitive to bank run than it is typical for corresponding banking sectors, and (iii) if the parent bank is more or less sensitive to the bank run than subsidiary banks.

Tab. 2 – Severity of the scenario “Bank run”. Source: Author’s calculation.

	04	05	06	07	08	09	10	11	12	13
Banks	-33.4	-26.2	-28.9	-37.7	-43.0	-62.6	-103	-87.6	-121	-76.8
Countries	-41.6	-36.5	-34.3	-35.1	-43.8	-40.4	-29.2	-42.7	-53.8	-50.0
Parent	-24.0	-9.4	-6.4	-6.9	-15.9	-13.2	-12.4	-13.6	-9.7	-8.3

As we can see from data in Tab. 2, banks belonging to the Societe Generale Group were as a whole less sensitive to the possible bank run during the first three years. However, the year 2007 was a turning point and banks became more vulnerable than corresponding banking sectors. The parent bank is on average much less sensitive than both subsidiary banks and banking sectors.

Focusing on the more detailed results in Appendix 3, the dispersion of the values of  $\Delta LIA$  is indeed significant as it ranges from 9 to 353% for individual banks and from 5 to 139% for

corresponding banking sectors. Answers to three defined research questions are presented in following text.

Which bank (and which banking sector) is the most vulnerable to the bank run? When it comes to the most vulnerable banking sectors, it was the Slovenian in the period 2004-2006 and the Polish banking sector in 2007-2013. In Poland, the liquidity started to decline in 2007 because of several reasons. Banks financed increased demand for loans also by the reduction of liquid assets; however, also some important structural weaknesses occurred: Polish banking sector as a whole became net borrower on the interbank market in 2008; household debts in foreign currency grew rapidly; and a very high loan-to-deposit ratio signalled that many banks are dependent on sources from the interbank market, while financing their lending activity. Also the impact of the financial crisis on the level of liquid asset ratio for Polish banks is statistically significant (Vodová, 2013b). Structural weaknesses for Slovenian banking sector at the beginning of the analyzed period were very similar: due to the high demand for foreign currency loans, banks restructured short-term foreign currency investments into long-term loans, which weakened the liquidity position of banks. The second adverse effect on the liquidity of the Slovenian banking sector was caused also by the shortening of average deposit maturity. These two factors together increased banks' dependence on the interbank funding (Bank of Slovenia, 2005, 2006). If we want to identify the most vulnerable banks, results are not surprising, as it mostly corresponds with the most vulnerable banking sectors. SKB Banka from Slovenia is the most sensitive bank in years 2004, 2006-2007, 2011 and 2013. Polish Euro Bank had the largest decline of LIA in years 2005, 2010 and 2012. Banka Societe Generale Albania complemented the group of most vulnerable banks in 2008 and 2009.

Are banks from the Societe Generale Group more or less sensitive to bank run than it is typical for corresponding banking sectors? Generally speaking, banks from this group are more sensitive to the bank run than corresponding banking sectors. This is especially true for Bulgaria, Macedonia, Moldova, Montenegro and Slovenia. On the contrary, less sensitive are only BRD - Group Societe Generale from Romania for the whole period and Komerční banka from the Czech Republic in period 2004-2009. This is consistent with our finding in Section 4.1 that, in most cases, liquidity of banks belonging to the Societe Generale Group is below average of the banking sector. If banks are less liquid, logically they are more vulnerable to any stress scenario, such as bank run.

Is the parent bank more or less sensitive to the bank run than subsidiary banks? Except of three banks in 2004 (SG - Splitska banka, Komerční banka and Ohridska banka), all subsidiary banks are more sensitive to the bank run than the parent bank. It again supports the hypothesis about intra-group support measures within Societe Generale Group, mentioned in Section 4.1.

## **5 CONCLUSION**

The aim of this paper was to measure the sensitivity of commercial banks from the Societe Generale Group to the bank run and to compare their sensitivity with average sensitivity of banks in particular countries.

We have used the methodology of scenario analysis for the liquid asset ratio. The results of the baseline values of the liquid asset ratio showed that beginning in 2007, the majority of banks belonging to the Societe Generale Group became less liquid than the parent bank. Moreover, subsidiaries banks are mostly less liquid than it is typical for corresponding banking sectors.

Then we have focused on the stress values of the liquid asset ratio. During first years of the analyzed period, with the only exception of Euro Bank in 2005, all banks would be able to face the bank run. However, the situation has completely changed during the financial crisis: only depositors of SG - Splitska banka, Komerčni banka, CB Mobiasbanca and BRD – Group Societe Generale would be able to withdraw 20% of their funds in the whole period 2008-2013. Other banks would not have enough liquidity to meet their requirements, at least in some years.

Finally, the results of the percentage change of the liquid asset ratio after the application of the stress scenario “bank run” enable us to answer three important questions:

Which bank (and which banking sector) is the most vulnerable to the bank run? When it comes to the most vulnerable banking sectors, it was the Slovenian in the period 2004-2006 and the Polish banking sector in 2007-2013. Both banking sectors suffered very similar structural weaknesses. The group of the most vulnerable banks consists from three banks: SKB Banka from Slovenia (in 2004, 2006-2007, 2011 and 2013, Euro Bank from Poland (in 2005, 2010 and 2012) and Banka Societe Generale Albania (in 2008 and 2009).

Are banks from the Societe Generale Group more or less sensitive to bank run than it is typical for corresponding banking sectors? Banks from this group are more sensitive to the bank run than corresponding banking sectors; this is especially true for Bulgaria, Macedonia, Moldova, Montenegro and Slovenia. On the contrary, less sensitive are only bank from Romania (for the whole period) and from the Czech Republic (in period 2004-2009).

Is the parent bank more or less sensitive to the bank run than subsidiary banks? Except of three banks in 2004 (SG - Splitska banka, Komerčni banka and Ohridska banka), all subsidiary banks are more sensitive to the bank run than the parent bank. These results may suggest that probably there were any types of upstream intra-group support measures.

## **PRACTICAL USE OF THE BOX-JENKINS METHODOLOGY FOR SEASONAL FINANCIAL DATA PREDICTION**

*Petr Klímek*

### **Abstract**

Many economic/financial processes exhibit some form of seasonality. The agricultural, construction, and travel sectors have obvious seasonal patterns resulting from their dependence on the weather. Similarly, the Christmas holiday season has a pronounced influence on the retail trade. In fact, seasonal variation of a series may account for the preponderance of its total variance. Forecasts that ignore important seasonal patterns will have a high variance. One of the possibilities to implement quality forecasts in the seasonal data is to use the Box-Jenkins methodology, which seems to be a useful tool for this purpose. The research study of this paper is devoted to application of ARIMA/SARIMA models to the seasonal financial data that are sensitive to the mean shifting while calculating the autocorrelation in the data. Results are compared with other common models with appropriate commentary.

*Keywords: Box-Jenkins Methodology, autocorrelation, partial autocorrelation function, seasonality, SARIMA models.*

JEL Classification: C29, C49, C58

### **1 INTRODUCTION**

Most financial data analysis processes and their conclusions are dependent on some fulfilled conditions. If they are not fulfilled all other calculations of means, confidence intervals, quantiles, statistical tests, Shewhart's charts, capability indices are questionable and not really correct (Kovarík & Klímek, 2012). These calculations usually offer incorrect and inaccurate results and conclusions. Therefore one should be very careful about above mentioned conditions (data normality, symmetry, etc.). Violations of assumptions for the application in different technologies are displayed in (Meloun & Militky, 2006). Mentioned conditions should be verified by the help of statistical tests. For instance, one can meet data asymmetry by the physical quantities such as strength or viscosity. Strong autocorrelation (dependence) can be met in continuous processes in finance, chemistry, pharmacy, food and metals. Quality of input process material can result into the mean shifting (Kovarík, 2012b).

Not normally distributed data can be seen in processes very often (Stephens, 2009). Data are very asymmetric with usually lognormal distribution. Classical regression concept assumes that the measured data are not auto-correlated. Even very low degree of data autocorrelation causes failure of classical regression analysis. This phenomenon is not unique in the case of continuous processes in time (financial processes, economic processes, climate processes, etc.). Autocorrelation of data becomes increasingly frequent phenomenon in terms of discrete processes, in economic and financial processes with short cycles (Kovarík, 2013). One of the ways to tackle auto-correlated data is the concept of stochastic modeling of time series using autoregressive integrated moving average models, the ARIMA model. The concept of linear stochastic autoregressive models (models AR), moving average (models MA), mixed models (the ARMA models), ARIMA models, or seasonal SARIMA models based on Box-Jenkins methodology is seen as a time series realization of a stochastic process (Montgomery & Friedman, 1989). The main aim of this paper is demonstrate practical usage of the Box-Jenkins methodology on case study of seasonal data prediction (monthly data will be given).

## 2 METHODOLOGY

The Box-Jenkins (Box & Jenkins, 1976) approach involves three basic activities:

1. Identifying the tentative model.
2. Determining the models parameters.
3. Testing/applying the model.

If the model developed in steps 2 and 3 does not meet expectations, the process is repeated and a new model is chosen and tested. The Box-Jenkins approach is more complicated than the other time series models, but this approach is also capable of handling almost any type of time series financial data. A number of studies comparing forecasting models indicate that the Box-Jenkins approach provides some of the more accurate short-range forecasts (one to three periods out) of any time series models.

The main features of the Box-Jenkins model are (Brockwell & Davis, 1996):

- 1) Its complexity discourages many forecasters and managers from using it.
- 2) It is best suited to short-range (i.e. daily, weekly or monthly) forecasts.
- 3) It requires a large amount of data (some authors feel at least sixty periods of data).
- 4) It is usually necessary to develop a new model whenever new sales data appear.

The linear models AR, ARMA and MA are modeling tool for the stationary processes. These models have a typical shape of the autocorrelation function (Autocorrelation Function – ACF) and partial autocorrelation function (Partial Autocorrelation Function – PACF), which are an essential tools for providing information about the stochastic process. ACF and PACF estimates are used to identify the time series model. Stationarity means that stochastic process has a constant mean value, constant variance and covariance structure of the second order invariant with respect to shifts in time (lags  $k$ ). Another desired property is called invertibility (interchangeability between different processes) (Dyer et al, 2003).

One can meet non-stationary processes in financial data very often. Nonstationarity can be present due to the mean value changing over time or process variance changing over time. It is a typical case of financial data (Enders, 2010).

ARIMA (Autoregressive Integrated Moving Average) is based on the principle of finding suitable time series model (Kovarik, 2011). The following part of methodology was also discussed in (Klimek, 2013). The general shape of the model ARIMA ( $p, d, q$ ) is

$$\Phi_p(B) \cdot \nabla^d \cdot x_t = \Theta_q(B) \varepsilon_t, \quad (1)$$

where  $\Phi_p(B) = (1 - \phi_1 B - \phi_2 B^2 \dots - \phi_p B^p)$  is autoregressive polynomial of  $p$ -th order,

and  $\Theta_q(B) = (1 - \theta_1 B - \theta_2 B^2 \dots - \theta_q B^q)$  is moving averages polynomial of  $q$ -th order,

$\nabla$  is an operator of backward difference (this term is introduced when the model exhibits non-stationarity of the process),

$d$  is difference order,

$t$  is time,

$B$  is back shift operator  $B \cdot x_t = (x_{t-1})$ ,

$\phi_1, \phi_2, \dots, \phi_p$  are parameters of autoregressive model,

$\theta_1, \theta_2, \dots, \theta_q$  are parameters of moving averages model,

$\varepsilon_t$  is called white noise, which is unpredictable fluctuations in the data, has a normal distribution with mean equal to zero and constant variance, and its values are not correlated. Residuals of model  $e_t = x_t - \hat{x}_t$  will be uncorrelated and normally distributed random variables (Kovarik, 2012a).

Most commonly used in applications are ARIMA models. Let us consider the model

$$x_t = \xi + \phi x_{t-1} + \varepsilon_t \quad (2)$$

where  $\xi$  and  $\phi$  are unknown parameters and  $\varepsilon_t$  is normally distributed and uncorrelated variable with the mean equal to zero and the constant standard deviation  $\sigma$ . This model is called autoregressive model of the first order and is denoted as AR (1). The values of the reference mark of quality which are mutually shifted of  $k$  time periods ( $x_t$  and  $x_{t-k}$ ) have the correlation coefficient  $\rho^k$ . This means that autocorrelation function ACF should fall exponentially. If the previous equation is expanded in the form

$$x_t = \xi + \phi_1 x_{t-1} + \phi_2 x_{t-2} + \varepsilon_t \quad (3)$$

One can get equation of second order autoregressive model AR (2). Generally, variable  $x_t$  is directly dependent on the values preceding  $x_{t-1}$ ,  $x_{t-2}$ , etc. in the autoregressive model AR (p). If the dependence of data using the random component  $\varepsilon_t$  is modeled, then moving average model MA (q) can be defined. Moving average model first order has an equation:

$$x_t = \mu + \varepsilon_t - \theta \varepsilon_{t-1} \quad (4)$$

There is some correlation only between two values  $x_t$  and  $x_{t-1}$ . It can be described as follows  $\rho_1 = -\theta / (1 + \theta^2)$ . This corresponds to the shape of the autocorrelation function ACF (Brooks, 2008). For the modeling of practical problems is often suitable a model compound containing both the autoregressive component and the moving averages component. This model is generally known as ARMA (p, q). Model ARMA of the first order, i.e. ARMA (1, 1) is described by the equation:

$$x_t = \xi + \phi x_{t-1} + \varepsilon_t - \theta \varepsilon_{t-1} \quad (5)$$

This model is often suitable for chemical and other continuous processes, where many quality characteristics can be easily modeled by the model AR (1). Measurement errors are described by random component of the model, which is assumed to be random and uncorrelated. The ARMA model assumes stationarity process i.e., that the character quality reference values are around a stable mean. There are also processes (e.g. in chemical industry, finance), where the values of monitored variable are running away. Then it is convenient to model processes using appropriate model with the operator of backward difference  $\nabla$ , such as the ARIMA model (0, 1, 1), the equation is

$$x_t = x_{t-1} + \varepsilon_t - \theta \varepsilon_{t-1} \quad (6)$$

Another important step in the use of ARIMA models is the choice of the appropriate type. When residuals testing determined that they are not auto-correlated and come from a normal distribution it is possible with them to verify whether or not the process is statistically stable (Klimek, 2013). Following Table 1 shows how to choose a right ARIMA model.

Tab. 1 – How to Choose a Right ARIMA Model. Source: (Arlt, 1999).

Model	Conditions		ACF	PACF
	Stationarity	Invertibility		
ARIMA (1,0,0) or AR (1)	$ \phi_1  < 1$	none	declining	1 significant PAC
ARIMA (2,0,0) or AR (2)	$\phi_1 + \phi_2 < 1$ $\phi_2 - \phi_1 < 1$ $-1 < \phi_2 < 1$	none	declining	2 significant PAC
ARIMA (0,0,1) or MA (1)	none	$ \theta_1  < 1$	1 significant AC	declining
ARIMA (0,0,2) or MA (2)	none	$\theta_1 + \theta_2 < 1$ $\theta_2 - \theta_1 < 1$ $-1 < \theta_2 < 1$	2 significant AC	declining
ARIMA (1,0,1) or ARMA (1,1)	$-1 < \phi_1 < 1$	$-1 < \theta_1 < 1$	declining	declining

Often time series possess a seasonal component that repeats every  $s$  observations. For monthly observations  $s = 12$  (12 in 1 year), for quarterly observations  $s = 4$  (4 in 1 year). In order to deal with seasonality, ARIMA processes have been generalized: SARIMA models have been formulated as follows:

$$\Phi(B)\Delta^d X_t = \Theta(B)\alpha_t \quad (7)$$

Where  $\alpha_t$  is such that

$${}_s\Phi(B^s)\Delta_s^D \alpha_t = {}_s\Theta(B^s)a_t \quad (8)$$

Hence

$$\Phi(B)_s \Phi(B^s)\Delta_s^D \Delta^d X_t = \Theta(B)_s \Theta(B^s)\alpha_t \quad (9)$$

And we write  $X_t \sim \text{ARIMA}(p, d, q) \times (P, D, Q)_s$ . The idea is that SARIMA are ARIMA  $(p, d, q)$  models whose residuals  $\alpha_t$  are ARIMA  $(P, D, Q)$ . With ARIMA  $(P, D, Q)$  we intend ARIMA models whose operators are defined on  $B^s$  and successive powers (Arlt, 1999).

Concepts of admissible regions SARIMA are analog to admissible regions for ARIMA processes they are just expressed in terms of  $B^s$  powers.

Now, consider some examples (special cases):

1.  $X_t = a_t - {}_s\Theta_1 a_{t-12}$  is ARIMA  $(0, 0, 0) \times (0, 0, 1)_{12}$ . There is only one seasonal MA component, specified by  $s = 12$ ,  $Q = 1$ . So, the ACF is characterized by finite extension and takes value only at lag  $k = 12$ . The PACF is infinite extended with exponential decay, visible at multiple 12 lags, which is alternate or monotonic according to the sign of  $\Theta_1$ .
2.  $X_t = {}_s\Phi_1 X_{t-12} + a_t$  is ARIMA  $(0, 0, 0) \times (1, 0, 0)_{12}$ . The seasonal AR component is specified by  $s = 12$ ,  $P = 1$ . So, the ACF is characterized by infinite extension. The PACF is with finite extended and takes value only at lag  $k = 12$ . (Arlt, 1999)

The last note is about advantages and disadvantages of the Box-Jenkins methodology.

The advantages:

- Stochastic models of ARMA are very flexible, so they are also applicable for time series very general forms.
- Can demonstrate a lot of successful applications.
- Software appearance of this methodology is now easily available in most econometric and statistical software systems.
- There is no better tool for routine analysis of serially correlated observations.

The disadvantages:

- Box-Jenkins methodology requires a longer time series (the minimum length of 50 observations is recommended, but this is not a problem for financial time series).
- Box-Jenkins methodology is essentially unworkable without a PC with corresponding software and without specific instruction.
- Practical interpretation constructed models can be difficult. The argument here are often numerical outputs (such as forecast) achieved using these models. (Cipra, 2008)

### **3 RESEARCH ON PRACTICAL USE OF BOX-JENKINS METHODOLOGY**

The task is to find a suitable model for the time series of **monthly** turnover of company XY (77 observations were available). The aim is to predict the future values of turnover for the next year – 12 forecast will be calculated using the Box-Jenkins methodology. Given results will be compared with other possible models.

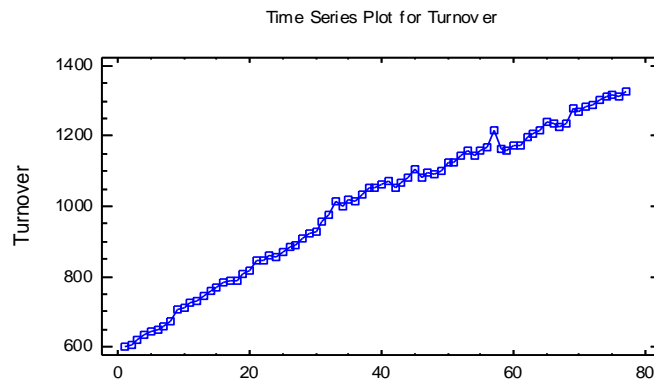

Fig. 1 – Time Series of Turnover. Source: Own Processing.

The time series is shown on the previous Fig. 1. All calculations are processed in Statgraphics Centurion 15 software tool. It is obvious from following figures that the time series is nonstationary, which is also confirmed by the shape of the ACF and PACF (Fig. 2) and periodogram (Fig. 3). At first sight, no seasonality in data is present.

Fig. 2 – ACF and PACF of Original Time Series. Source: Own Processing.

Fig. 3 – Residual Periodogram of Original Time Series. Source: Own Processing.

As the values of ACF are declining slowly, the first values by ACF and PACF are very close to one and the periodogram has a significant peak at zero (not seasonal) frequency, we can assume that the time series is of  $ARIMA(0, 1, 0)_c$  and therefore must be stationarized by the first differences. This conclusion is confirmed by the graph of turnover periodogram (Fig. 3), as well as the residual ACF and PACF of the model (Fig. 2), whose values lie outside the tolerance limits. Therefore the model  $ARIMA(0, 1, 0)_c$  (with constant) will be calculated first. Results are depicted in Fig. 4 and Fig. 5, and also in Table 2.

Fig. 5 – Residual ACF and PACF of Model ARIMA (0, 1, 0)<sub>c</sub>. Source: Own Processing.

Residuals and residual periodogram of time series for nonseasonal difference appear in the Fig. 4. It is evident that the time series is stationary after nonseasonal difference. This is also confirmed by the periodogram (Fig. 4). It is clear from the Fig. 4 that the time series contains significant **seasonal** component. The presence of a seasonal component is also confirmed by the residual ACF and PACFs (Fig. 5). Both functions have a statistically significant every negative eleventh value, and every positive twelfth value and at the same time it is also significant the first value. For this reason, the model must be extended for a part of the AR (1). The model ARIMA (1, 1, 0)<sub>c</sub> will be estimated. The results are shown in Table 3.

Fig. 8 – Residual ACF and PACF of Model SARIMA (1, 1, 0) (1, 0, 0)<sub>c</sub>. Source: Own Processing.

Although the values of residual ACF and PAFCs (Fig. 8) decreased, and the value P-value Box-Pierce test increased (0.750122) we can conclude from t-tests (Tab. 4) that the part AR (1) does not belong to estimated model (P-value = 0.932531) and therefore should be excluded from model. Therefore the model SARIMA (0, 1, 0) (1, 0, 0)<sub>c</sub> without AR(1) will be next estimated in Table 5.

Fig. 9 – Residual ACF and PACF of Model SARIMA (0, 1, 0) (1, 0, 0)<sub>c</sub>. Source: Own Processing.

The residual ACF and PACFs (Fig. 9) has not been significantly reduced compared to Fig. 8, but it can be assumed that the residuals have stochastic character. It confirms also the P-value of the Box-Pierce test (0.796356) and other test of randomness. Partial t-test shows that P-values of parameters  $\Phi_1$  (0.00000) and  $\mu$  (0.053863) are lower than a significance level  $\alpha$  (0.05). Table 5 shows that all parameters are significantly different from zero (statistically significant) and the estimated model has the form

$$(1 - 0.798634^{12}) \times (1 - B)y_t = 1.762612 + a_t \quad (10)$$

It can be expressed alternatively as:

$$y_t = 1.762628 + y_{t-1} + 0.798634y_{t-12} - 0.798634y_{t-13} + a_t \quad (11)$$

Table 6 contains the point and interval forecasts of the monthly time series for the next year.

## 4 RESULTS AND DISCUSSION

The Box-Jenkins data approach was applied to seasonal financial data of turnover of company XY (totally 77 observations were given). The time series given was non-stationary, which

was confirmed by the shape of the ACF and PACF and also by the shape of residuals periodogram. The original time series was stationarized by the first differences. Final model SARIMA (0, 1, 0) (0, 1, 0)<sub>c</sub> was chosen according to Box-Jenkins methodology. Comparison with other models is shown in Table 7. Model SARIMA (0, 1, 0) (0, 1, 0)<sub>c</sub> was detected as the best model among compared ones (linear trend, simple exponential smoothing and Brown's exponential smoothing). The other models were chosen automatically by statistical software as appropriate to given data. All SARIMA model parameters were considered as statistically significant. As well as the value of P-value of the Box-Pierce test and test of randomness were very high. That values indicated that the model residuals were of white noise (main condition of use this method). Therefore this model can be used for the forecasting purpose. The process can be regarded as if it is stationary.

Tab. 7 – Model Comparison. Source: Own Processing.

<b>Model Comparison</b>					
Data variable: Turnover					
Number of observations = 77					
Length of seasonality = 12					
<b>Models</b>					
(A) ARIMA(0,1,0)x(1,0,0) <sub>12</sub> with constant					
(B) Linear trend = 633,764 + 9,43593 t					
Seasonal adjustment: Multiplicative					
(C) Simple exponential smoothing with alpha = 0,9999					
Seasonal adjustment: Multiplicative					
(D) Brown's linear exp. smoothing with alpha = 0,5892					
Seasonal adjustment: Multiplicative					
<b>Estimation Period</b>					
<i>Model</i>	<i>RMSE</i>	<i>MAE</i>	<i>MAPE</i>	<i>ME</i>	<i>MPE</i>
(A)	<b>10,565</b>	7,63222	<b>0,711802</b>	-0,369181	- <b>0,0251995</b>
(B)	31,0063	23,622	2,47717	- 0,00490717	-0,203619
(C)	13,8293	11,1484	1,16115	9,30716	1,00733
(D)	10,5782	7,34392	0,745923	0,48169	0,0994422
<i>Model</i>	<i>RMSE</i>	<i>RUNS</i>	<i>RUNM</i>	<i>AUTO</i>	<i>MEAN</i>
(A)	<b>10,565</b>	<b>OK</b>	<b>OK</b>	<b>OK</b>	<b>OK</b>
(B)	31,0063	***	***	***	OK
(C)	13,8293	OK	OK	**	*
(D)	10,5782	OK	OK	**	OK
<b>Key:</b>					
RMSE = Root Mean Squared Error					
RUNS = Test for excessive runs up and down					
RUNM = Test for excessive runs above and below median					
AUTO = Box-Pierce test for excessive autocorrelation					
MEAN = Test for difference in mean 1st half to 2nd half					
OK = not significant (p >= 0,05)					
* = marginally significant (0,01 < p <= 0,05)					
** = significant (0,001 < p <= 0,01)					
*** = highly significant (p <= 0,001)					

This Table 7 compares the results of four different forecasting models. Looking at the error statistics (RMSE, MAE, MAPE, ME, and MPE), the model with the smallest root mean squared error (RMSE) during the estimation period is model A. The model with the smallest mean absolute error (MPE) is model A. The model with the smallest mean absolute percentage error (MAPE) is also model A. These results can be used to select the most appropriate model for researcher's needs. Model A is the best among tested models. The Table 7 also summarizes the results of four tests run on the residuals to determine whether each model is adequate for the data. An OK means that the model passes the test. One asterisk means that it fails at the 95% confidence level. Two asterisks mean that it fails at the 99% confidence level. Three asterisks mean that it fails at the 99.9% confidence level. It can be concluded that the currently selected model, model A (SARIMA (0, 1, 0) (1, 0, 0)<sub>c</sub>), passed all 4 tests.

It can be summed up that the model SARIMA (0, 1, 0) (1, 0, 0)<sub>c</sub> was detected as the best model among compared ones in Table 7. The values of RMSE, MAPE, and MPE were the smallest and all tests about randomness of residuals were fulfilled satisfactory (OK in all columns).

Therefore SARIMA model can be regarded as suitable statistical tool for forecasting of seasonal financial data (turnover).

## 5 CONCLUSION

The traditional regression procedures are grounded on the assumption that the process observations being monitored are independent and identically distributed. The assumption of independence is usually violated. Autocorrelation among measurements becomes an inherent characteristic of a stable process. This autocorrelation causes significant deterioration in regression analysis. To address this problem, several approaches for handling auto-correlated processes have been proposed. The most popular procedure utilizes ARIMA or SARIMA model. The Box-Jenkins methodology represents a modern concept analysis of stationary and non-stationary time series based on probability theory. This paper mainly focused on the detection of seasonality of auto-correlated processes.

This paper dealt with stochastic models applications in seasonal financial data. This kind of data is very sensitive to mean shifting and strong autocorrelation appears very often. The Box-Jenkins methodology containing ARIMA and SARIMA models was applied to given seasonal financial data as satisfactory model for forecasting.

Totally, 77 observations were available. The requirement of minimal size of data (50) was fulfilled. Results were compared with other common models (linear trend, simple exponential smoothing and Brown's exponential smoothing). The Box-Jenkins methodology was detected as the best model for seasonal financial data due to its ability to fit given data.

## **CURRENT TRENDS IN THE FACTORING MARKET IN THE WORLD AND IN THE SLOVAK REPUBLIC**

*Koišová Eva, Ivanová Eva*

### **Abstract**

For all enterprises, whether small, medium or large, the issue of financing their business activities is very significant. Apart from standard forms of financing, enterprises can use alternative methods such as leasing, venture capital, factoring and forfeiting. The purpose of the paper is to analyse and assess the current state and development of factoring market in the world and in the Slovak Republic. In section 1, key terms in factoring are defined and main characteristics are provided which draw upon theoretical background regarding factoring as an alternative source of financing. In the empirical part, factoring activities in the world and in the Slovak Republic are analysed. The main data sources are the databases of the Factors Chain International and Association of Factoring Companies in the Slovak Republic. Research data reveal that factoring increased by more than 73% worldwide in 2013, and factoring business has not yet experienced economic crisis. From a regional perspective, Europe is the largest factoring market. VÚB Group was the leading factoring company in the Slovak Republic whose share in the total turnover amounted to more than 48% in 2013.

*Keywords: factoring, domestic factoring, international factoring, recourse factoring, factoring without recourse, forms of factoring.*

JEL Classification: G21, G23

### **1 INTRODUCTION**

Factoring is a modern tool to finance an enterprise on a short-term basis by accelerating the breakdown of liabilities, while not raising the debt of an enterprise. The history of factoring dates back to the days of moneylenders in the middle ages. It has taken on a new life in recent years as a financing method for many businesses in the world. (Mazurek, 2010)

This tool is used by enterprises when financial resources are needed before the maturity of their receivables. Sedláčiková, Volčko, Jelačić (2014) write that this method mainly includes protection before customers' insolvency, management of receivables, as well as the opportunity to dispose with the funds before the end of the maturity of receivables.

Factoring is an advantageous tool since it is also available for enterprises that do not qualify for a bank loan, such as enterprises with a higher risk level profile or start-ups. When using factoring, the credit debt of enterprises is not increased and enterprises' assets do not have to be secured. The disadvantages of factoring include its higher cost. Factoring is usually more costly than the traditional borrowing. Factoring is used to refinance domestic market liabilities with maturity of 180 days. (Ukey, 2014)

Recently, factoring service companies have been increasingly focusing on small and medium-sized enterprises (Belanová, 2012). Large-sized companies offer a high turnover, yet a smaller margin for factoring service companies. It is the small and medium-sized enterprises using factoring services to finance their operational needs; therefore they represent a great potential for factoring service companies. On the other hand, the primary criterion to choose the factoring service company is currently its funding limit. Thus, the amount of finance to be

provided by a factoring company is of primary concern, while the price comes second. It is, however, not common for Slovak enterprises to use factoring services. Factoring as a percentage of GDP stands at around 6% abroad, compared to a mere 2% in Slovakia. The purpose of the paper is to analyse and assess the current state and development of factoring market in the world and in the Slovak Republic.

## **2 MATERIALS AND METHODOLOGY**

The main purpose of the paper is to analyse and assess the current state and development of factoring market in the world and in the Slovak Republic. In addition, theoretical approaches to and characteristics of factoring are discussed. Moreover, worldwide factoring turnover in the period of 2009-2013 and the situation in the Slovak factoring market over 2012-2014 are analysed.

Statistical methods were utilized to analyse the use of factoring services worldwide and in the Slovak Republic. Moreover, base index and percentage indicators were used to make a more thorough analysis of the issue. In addition to analysis as the main research method, synthesis, comparison and compilation were employed. The methodology closely corresponds to the objective of the paper. The main data sources are the databases of the Factors Chain International, Association of Factoring Companies in the Slovak Republic, and knowledge compiled from several authors.

## **3 CHARACTERISTICS OF FACTORING**

Factoring has played an important role in the market economy. The word “Factor” means the broker, agent, intermediary. (Adamova, K., 2013) The term has been defined in a number of ways in technical; some authors consider factoring as one of the alternative sources of finance for business growth (Belás, 2010); while others discuss individual financing methods under various circumstances. (Kislingerová, E. et al., 2007)

Belás et al. (2010) and Vlachynský et al. (2012) define factoring as the purchase of short-term trade receivables prior to their maturity date. In principle, it is dealt with the provision of a short-term loan by a factor (bank). Kislingerová (2007) delineates factoring as “...a regular purchase of short-term receivables by a factoring company.” Hyránek, Jánošová (2009) as well as other authors (2000) view factoring as an option to finance businesses on a short-term basis in a both domestic and international trade based on the contractually agreed purchase of short-term receivables associated with the provision of unsecured business loans. In their definitions, Slovak and Czech authors draw upon the definitions discussed in foreign literature.

There are three parties involved in factoring, such as the factor, the one who sells the receivable and the debtor as illustrated in Figure 1. The contract of factoring is accomplished between one party whose main activity is to be the supplier of goods and another party who is a factor.

As a matter of fact, factoring is the purchase of outstanding receivables which arise from the sale of products and services by a factoring company (factor). By purchasing receivables, the factor finances the client and assumes the risk associated with the collection of the receivable. (Vlachynský et al., 1999, p. 170) Transactions are performed in the form of cession of receivables from the original creditor (supplier) to a factoring company. This is normally performed by transferring invoices from the original creditor to a factoring company. Thus, the sale of invoices transfers the deed of the invoices to the factor. The original creditor will receive cash advance to settle the receivable in question by the factor, who will also assume

responsibility for the receivable collection and in some cases the credit risk. The amount of advance varies, but normally it is 60-80% of the invoiced sum. Cash advances can be received almost immediately; upon receiving the necessary documentation to purchase the receivable. Once the customer (debtor) pays the account receivable in full to the factoring company account, the account receivable is settled with the supplier while the sum paid is reduced by the interest, factoring fee and commission. Factoring depends on various circumstances (in particular financial) affecting factoring services, and demonstrated in the cooperation between a supplier and factor.

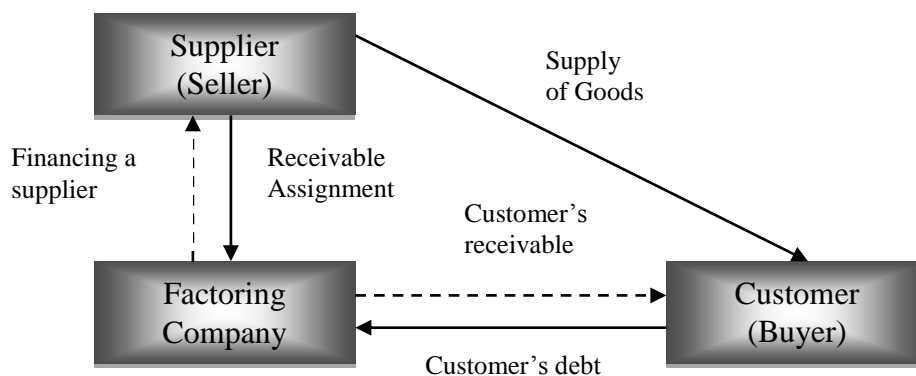

Fig. 1 Accounts receivable factoring flow Source: Elaborated by authors according to Smejkal, V. – Rais, K. (2010)

In practice, there are various factoring forms. The key aspects to classify factoring are as follows: risk of non-payment the receivable, notification on the receivable assignment, scope of cooperation between the factoring company and the enterprise, and the territorial aspect.

There are two types of invoice factoring to choose from; real factoring (factoring without recourse) and false (recourse) factoring. In a non-recourse agreement, the factoring company takes on any unpaid debts, and is usually concluded with established suppliers. The factor must look at the creditworthiness and financial situation of the customer as the factor completely assumes the risk of non-payment by the customer. Non-recourse factoring insulates enterprises from the cost of bad debt and the factor is more concerned with the creditworthiness and overall financial indicators related to the supplier's asset structure. Under non-recourse factoring, the factor bears the complete risk of bad debts arising from non-payment -payment of dues by the customer. For bearing this risk, the factor charges an additional del credere commission. Recourse (false) factoring is fit for manufacturing industries and businesses that need to stabilize their cash flows and extend the due dates of invoices for their customers. Under recourse factoring, the supplier cooperates with the customer on a long-term basis, knows their payment behaviour and intends to improve their business terms and conditions. After the expiry of the receivable due date, the factor may assign the receivable back to the supplier. Thus, the risk of non-payment is borne by the enterprise, and if the customer fails to pay, the enterprise must pay back the purchased amount of the receivable.

According to the debtor's awareness regarding cession, two types of factoring are mainly distinguished. In the open factoring, the customer is informed about the cession of the claim to the factor. Open factoring is quite common, whereas the other type – closed factoring – is

not so popular. Under closed factoring, the customer is not informed regarding the cession of the claim and pays to the account given on the supplier's invoice being already the factor's account. According to the country of location of the parties involved in the transaction, domestic factoring and international factoring are distinguished. In the case of international factoring, supplier, customer and factor are not registered in the same state.

In summary, suppliers use factoring services for several reasons. Suppliers opt for factoring services when they want a factoring company to maintain their accounts in respect of customers' invoices, funding, granting credit to the suppliers, etc. Factoring companies provide services related to refinancing commercial loans. Before the factoring companies accept the assignment of receivables, they verify the debtor's capability to settle the debt, creditworthiness of debt as well as its size.

#### **4 DEVELOPMENT OF THE FACTORING TRADE VOLUME AND ITS ANALYSIS**

In the sixties of the twentieth century, there was a sharp increase in the usage of factoring when various types of services regarding the purchase of goods "on credit" became widespread. Purchases by credit cards, leasing, forfaiting and factoring also became very popular. Moreover, new ways of doing business activities and their funding, including using computer technology in banking helped accelerate the strides in the factoring market. Slovak enterprises have discovered the advantages of this method of financing. The factoring added value is still not quite understood, meaning that factoring is not just about financing of receivables. (Sedliačiková, Volčko, Jelačić, 2014)

##### **4.1 Development of factoring in the world**

Factoring penetrated into Europe in the early seventies. At around the same time, factoring companies started to form chains with international scope. One of the biggest is the Factors Chain International (FCI). FCI brings together factoring organizations from all over the world cooperating in performing various types of factoring transactions. Currently, an increasing growth of factoring trades has been observed. The growth of factoring business can be attributed to the ever increasing number of factoring chain members, thus a growing awareness of factoring in the world. The latest statistical data indicate that there was a slight increase of factoring turnover compared to 2012 in the world which stood at approximately 5%. From 2009 to 2013, factoring turnover rose by 73.75%. While in 2009 the overall factoring turnover was €1,284 billion, it rose to €2,231 billion in 2013. It follows that the factoring turnover rose moderately despite the economic crisis. The development of factoring turnover is shown in Fig. 2.

Fig. 2 Development of the world factoring turnover in 2009-2013 in billion Euro. Source: Elaborated by authors according to Table 1.

It follows from Table 1 that a significant share of the world factoring turnover was world domestic factoring, and the highest turnover was of € 1,828 billion in 2013. The world international factoring was on the rise over the period 2009-2013, and its share in the world factoring turnover was 13% in 2009 and reached even 18% in 2013.

Tab. 1 Development of the world factoring turnover in 2009-2013 in billion Euro. Source: Authors' calculations according to FCI data available on <http://www.fci.nl/news/detail/?id=502>

Year	Domestic	International	Total	Base index in %
<b>2009</b>	1,118	166	<b>1,284</b>	100.00
<b>2010</b>	1,402	246	<b>1,648</b>	128.35
<b>2011</b>	1,741	274	<b>2,015</b>	156.93
<b>2012</b>	1,779	353	<b>2,132</b>	166.04
<b>2013</b>	1,828	403	<b>2,231</b>	173.75

From the geographic point of view, Europe has the most important share of world factoring whose volume amounted to more than 60%. It has to be noted, however, that international factoring increased by more than 242%. Thus, the international factoring activity is more dynamic than the domestic factoring activity which rose by 163.5% compared to 2009. China played a major role in factoring business whose percentage share in factoring turnover amounted to approximately 54%, thus becoming one of the leaders in the worldwide factoring market.

Fig. 3 Development of factoring trades by continents in 2013. Source: Elaborated by authors according to FCI data available on <http://www.fci.nl/news/detail/?id=502>

The volume of factoring transactions in the world factoring is highest in Europe (61%), followed by Asia (27%) and America (8%) as shown in Figure 3. Other important European representatives in the factoring market include the United Kingdom, France, Italy, Germany and Spain.

Even though domestic factoring turnover constitutes a significant share of the world factoring turnover, the world factoring activity lessens its importance since the global capital blurs the boundaries of individual economies, which affect the commercial transactions made by individual enterprises. This is why the world factoring is growing in such a dynamic and fast way. The strongest players in the global factoring market are Asian countries, mainly China, Japan, Taiwan and Hong Kong.

#### **4.2 Development of factoring activity in the Slovak Republic**

In the Slovak Republic, factoring companies are members of the Association of the Factoring Companies of the Slovak Republic (AFS SR) that was founded in March, 2003. Their founding members include VÚB Factoring, Transfinance Slovakia, Tatra banka, OB Heller, Factoring Slovenskej sporiteľne (SLSP) and OTP Factoring Slovakia.

According to the data provided by the Association of the factoring companies of the Slovak Republic over the period of 2012-2014, factoring services were provided by VÚB Group, Tatra banka, ČSOB Group, SLSP Group, Bibby Factoring and Eximbanka. The data on the total factoring turnover in the Slovak Republic are listed in Table 2 and illustrated in Figure 4. Cumulative data for 1Q and 2Q were available for 2014.

Tab. 2 Total turnover from factoring services in the SR in billion Eur. Source: Elaborated by authors according to AFS data

Company	2012	2013	2014*	Share in % in total turnover in 2012	Share in % in total turnover in 2013	Share in % in total turnover in 2014
VÚB Group	705	749	195	39.36	48.17	32.55
Tatra banka	455	378	228	25.40	24.31	38.06
ČSOB Group	231	211	69	12.90	13.57	11.52
SLSP Group	375	168	93	20.94	10.80	15.53
Bibby Factoring	25	31	14	1.40	1.99	2.34
Eximbanka		18	0		1.16	0.00
<b>Total</b>	<b>1,791</b>	<b>1,555</b>	<b>599</b>	100.00	100.00	100.00

\*Data for 2014 are cumulative data for Q1+Q2

From 2012 to 2013, VÚB Group was the leading factoring company whose share in the total factoring turnover amounted to 48.17% in 2013. VÚB Group managed to increase its year-to-year market share by 9%, which indicates that it financed almost every second trade receivable in Slovakia. A slight drop was registered with Tatra banka, whereas SLSP Group registered a dramatic drop from 20.94% in 2012 to 10.80% in 2013. In 2014, Tatra banka was the leading factoring player with total turnover of €228 million, followed by VÚB Group with a mere €195 million. According to available data, Eximbanka had no turnover.

Fig. 4 Share in the total factoring turnover by Slovak factoring companies in 2012-2014 in %.  
Source: Elaborated by authors according to Table 2

Overall, however, the factoring business was the most prosperous in 2012, while there was a decrease by 13.18% in 2013 compared to 2012 and there will apparently be a slight decline according to available statistical data in 2014. In Slovakia, factoring services are mainly

provided by banking institutions. The only Slovak non-banking company is the Bibby Factoring company. Factoring services are primarily used by small and medium-sized enterprises, yet their use is still lagging behind the use in developed countries. Slovak companies are only learning how to use this alternative source of funding.

While investigating factoring turnover in terms of non-payment risk, we looked at the development of recourse and non-recourse factoring (Tab. 3 and 4). Under recourse factoring, the biggest turnover over the period 2012-2014 was reached by Tatra banka, followed by VÚB banka and ČSOB Group. Sale volume was the highest in 2012 and amounted to €534 million Eur. In 2013, there was a decline in sale volume by approximately 10% and according to the data available for the Q1 and Q2 2014, further decline can be expected.

Tab. 3 Development of recourse factoring in million Euro

Company	2012	2013	2014*
VÚB Group	122	135	44
Tatra banka	280	199	160
ČSOB Group	73	94	22
SLSP Group	43	39	24
Bibby Factoring	16	21	10
Eximbanka	0	0	0
<b>Total</b>	<b>534</b>	<b>483</b>	<b>260</b>

*\*Data for 2014 are cumulative data for Q1+Q2*

Under the factoring without recourse, the situation is different. In 2013, factoring without recourse reached €515 million, which is by 19.5% higher than in 2012 and the factoring turnover might be higher in 2014. Under the factoring without recourse, the leading company is VÚB Group. In 2013, VÚB Group increased their turnover even by 236.8% compared to 2012. Sound development is registered in Q1 and Q2 2014.

Tab. 4 Development of factoring without recourse in million Euro

Company	2012	2013	2014*
VÚB Group	87	206	116
Tatra banka	201	126	67
ČSOB Group	55	98	46
SLSP Group	2	77	69
Bibby Factoring	8	9	4
Eximbanka	0	0	0
<b>Total</b>	<b>431</b>	<b>515</b>	<b>302</b>

*\* Data for 2014 are cumulative data for Q1+Q2*

In the Slovak Republic, there are no major differences in the development of both types of factoring, even though factoring without recourse tends to grow faster. Factoring services are not that widespread among enterprises in the Slovak Republic when compared to developed countries, or even the Czech Republic, Poland and Hungary. The low level of factoring activity in the Slovak economy might be ascribed to insufficient financial literacy of small and medium-sized enterprises that prefer using more traditional financing methods. Additionally, Pavlát and Schlossberger (2014) point out that small and medium-sized

companies face informational opacity regarding factoring terms, conditions as well as fees and charges.

## **5 CONCLUSION**

Rising importance of factoring services and differences in factoring turnover across countries can be attributed to economic performance of the respective country. The stronger and developed economy, the more frequently alternative methods to finance companies are utilized. Factoring services are becoming more widespread and provided almost exclusively by banks. According to the Association of the Factoring Companies there is only one non-bank institution providing factoring services – Bibby Factoring Slovakia – reaching the lowest turnover in the factoring industry.

From 2012 to 2013, VÚB Group was the leading factoring company whose share in the total turnover amounted to 48.17% in 2013. VÚB Group managed to increase its year-to-year market share by 9%, and is the leader in factoring without recourse. A slight drop was registered with Tatra banka, whereas SLSP Group experienced a dramatic drop from 20.94% in 2012 to 10.80% in 2013. In 2014, Tatra banka was the leading factoring player with the total turnover of €228 million, followed by VÚB Group with a mere €195 million.

From the geographic point of view, Europe has the most important share of the world factoring whose volume amounted to more than 60%. It has to be noted, however, that international factoring increased by more than 242%. Thus, the international factoring is more dynamic than the domestic factoring which rose by 163.5% compared to 2009. Europe is composed of many industrialized countries where the volume of factoring activity is high. Important European representatives in the factoring market include the United Kingdom, France, Italy, Germany and Spain.

The volume of factoring activity is low in the former communist countries. The highest factoring turnover was reached in large countries, namely Poland in 2011 (€12,000 million) and Russia (€8,580 million). The lowest factoring turnover was reached in Bosnia and Herzegovina, Bulgaria and Serbia. In terms of the number of factoring companies, the Slovak Republic is comparable with the Czech Republic (8), Lithuania (8), Latvia (7), and Serbia (9). In terms of factoring turnover, Slovakia is lagging behind the Czech Republic (€3,760 million) and Lithuania (€1,755 million).

Following the data from 2011, the factoring activity in America is lower than in Europe. This is mainly due to the rapid rise in factoring only in Brazil and Chile. In addition, factoring activity is growing in Canada, Columbia and Mexico, although the leading country with the highest factoring turnover remains the USA (€80,000 million).

African countries do not play a significant role in the factoring market. Factoring activity, however, is quite widespread in the Republic of South Africa (turnover of €13,500 million). The strongest players in global factoring market include Asian countries, mainly China, Japan, Taiwan and Hong Kong.

Even though factoring transactions are becoming more popular, the main disadvantages regarding factoring are the following:

- availability of other types of financing enterprises,
- established traditional forms of financing, such as bank loans,
- customer's consent with factoring services is required (assignment clause on the invoice),

- minimum limits on the volume of the assigned receivables - this hinders mainly small and medium-sized enterprises which are unable to reach the minimum annual limit of financial resources,
- higher costs associated with factoring services when compared to a bank loan.

## **ANALYSIS OF CZECH COMPANIES' DEPARTURES TO TAX HAVENS AND THEIR EFFECT ON CZECH ECONOMY**

*Eva Kolářová, Eva Kuderová*

### **Abstract**

The minimum taxation and the maximum anonymity of owners and managers are the reasons why to move a company to a tax haven. States strive to legally make it more complicated to transfer incomes to tax havens but they are not very successful. According to the World Bank, almost a half of the global GDP is in tax havens. The research deals with the analysis and consequent evaluation of Czech companies' departure to tax havens. It deals with numerous comparisons of values but especially with the number of tax payments and time exigency.

*Keywords: tax haven, tax planning, income tax of legal entities*

JEL Classification: H 26

### **1 INTRODUCTION**

Taxhavens originated with tax collection as early as in Antique Greece. At the Medieval merchants with the seat in the London City were exempt from tax in London. Flanders in Belgium was the tax haven from the 16<sup>th</sup> to the 18<sup>th</sup> century. Tax havens are most frequently used for transferring the income from a country with high taxes.

Tax havens and off-shore centres are currently one of the essential obstacles for the development both at the international and the Czech Republic level. According to the data of Jens Martens and Wolfgang Obenland (2011), German experts, published in the Um Steuern study, the Czech Republic belongs among the countries with the highest capital outflow. This value is not counted according to the number of inhabitants, but in absolute numbers. Between 2000 and 2008 CZK 140 billion in average disappeared from the Czech Republic without being taxed. According to the cautious estimates the Czech Republic lost CZK 30 billion on taxes (HAMPL, 2013). We also have to include the loss of the multiplication effect of money which was withdrawn from the economy without taking part in the creation of further values, and also the payment of the excise tax at the minimum amount of CZK 10 billion. In general, we can state the economy loses at least 60 thousand job positions by this fact.

### **2 GOAL AND METHODOLOGY**

The goal of this article is to analyse reasons for Czech companies' departure to tax havens. Main methods used in this article are the method of complete analysis of the current state of tax havens and the development of companies' departures to tax havens since 2007. This year was selected due to the start of the crisis in the Czech Republic. The main goal was to determine the effects acting on companies to think of the departure to destinations with lower tax burden.

#### **2.1 Negative Effect of Tax Havens**

Multinational companies especially use tax havens in the field of intellectual property. These companies can decide to a large extent where research and development will be implemented with the goal to ensure the flow of licence fees to a jurisdiction with lower tax. In compliance

with this strategy, Desai et al. (2006) gave the evidence that multinational companies in the U.S.A. which focused on research and development were more probable to found branches in tax havens.

The other view of these problems seems to be supported with recent experience in income from taxes of legal entities. Despite the high amount of direct foreign investments to tax havens, the revenues from income tax of legal entities in the U.S.A., Great Britain and other capital-exporting countries have not dropped, but in fact they have increased. This fact indicates that concerns expressed in harmful impacts of tax havens can be relatively exaggerated.

Desai et al (2006) created a model in which there is a complementarity between investments in the tax haven and investments in neighbouring countries with high taxation. On the one hand, an investment in a country with high taxation induces demand for operations in the tax haven for the purpose of reducing the income tax liability. On the other hand, the presence of the tax haven enables tax planning which reduces costs of investments in neighbouring countries with high taxation. This implies that it can be reasonable to believe that major world economies take advantage of the existence of tax havens. This fact is supported by the models of Keen, Dessai, Hong and Smart (Keen, 2001, Desai et al., 2006, Hong and Smart, 2007) which state under what conditions corporate activities of a tax haven can be beneficial for domestic countries of multinational companies. Tax planning of multinational companies (e.g. obtaining income in a tax haven through interest stripping) reduces their efficient tax rates and makes them more willing to invest in countries with high taxation.

## **2.2 Positive Effect of Tax Havens**

Tax havens can act positively in the field of tax competition. As shown by Weichenrieder (2005), statutory tax rates for legal entities have significantly decreased in Europe in recent decades. The presence of an international tax planning provides the countries with high taxation the possibility to maintain or even increase entrepreneurial tax and valid tax rates on capital if initial tax rates are not too high and at the same time to protect the outflow of direct foreign investments (Hong and Smart, 2010).

## **2.3 Transparency of Tax Havens**

The interest in tax havens reflects their disproportionately high role in the world economy, especially in relation to international capital flows. Tax havens are one of the central topics of current political debates in the field of taxes, including the scope of international tax competition (Slemrod and Wilson, 2009, Dharmapala, 2008) as well as activities of avoiding paying the tax by enterprises (Desai et al., 2006).

Tax havens have been recently paid a higher attention to as proven by initiatives of the Organisation for Economic Co-operation and Development (OECD, 1998, 2000, 2004). The reason is to support the efficient exchange of information between tax authorities of different countries. Within the initiative of OECD (2000) a list of countries and territories has been created which are considered to be tax havens. They include e.g. Belize, the British Virgin Islands, Gibraltar, Hong-Kong, Jersey, the Marshall Islands, the United Arab Emirates, St. Vincent and Grenadines, the U.S.A.

In the following years most of these havens agreed on the improvement of transparency of their tax systems and facilitated the exchange of information. Nonetheless, the scope of sharing the information in practice is unclear and the impact of this initiative is doubtful. Since 2013 OECD has not extended the list of countries considered the tax haven. However, Luxembourg, Cyprus, the British Virgin Islands and the Seychelles do not meet international

standards for tax transparency. It follows from the report published by the Global Forum on Transparency and Information Exchange for Tax Purposes which forms part of the Economic Co-operation and Development (OECD) and which focuses on fighting against tax havens.

Kudrle (2008) studied the total foreign portfolio investments (disclosed by the Bank for International Payments) at the Cayman Islands. His analysis of time series does not find any significant impact of this OECD initiative. Bucovetsky and Haufler (2008) who studied the efforts of Ireland to attract headquarter operations implemented in Europe, came to similar conclusions. They detected a very weak political response by the European Union, despite the proven willingness of member states to harmonise tax policies in other areas.

### **3 ONSHORE AND OFFSHORE COUNTRIES**

#### **3.1 Characteristics and Division of Tax Havens**

OECD considers a tax haven to be a jurisdiction which meets certain criteria:

- It has nominal or zero taxes,
- It shows a lack of transparency,
- It has laws or administrative procedures which prevent efficient exchange of information with the governments of countries whose residents obtain tax advantages in the jurisdiction.

OECD carefully monitors the countries which are considered to be tax havens and it issues their list divided to three “lists”. The black list has been empty since the half of 2009. The longest list is the grey one which contains countries (e.g. Malaysia, Belize, the Philippines etc.) which promised implementing the rules for the exchange of tax information but has not implemented them in their system of law. The third list is the white one which contains countries which have implemented the rules of OECD in their systems of law regarding the transparency and the exchange of information in tax issues and which adhere to them (e.g., among others, the Seychelles, the Czech Republic, the Netherlands and most the other states of the EU).

For a country to be transferred from the grey list to the white list, 12 agreements on the exchange of information in tax matters must be concluded.

#### **3.2 Onshore Countries Used in International Tax Planning**

Onshore destinations are often sought for because of their economic, social and political stability. The system of law is usually simpler, clearer and more easily enforceable for companies. Companies operating in these onshore destinations act seriously. The tax advantage usually rests in a lower tax burden in the selected type of tax. The table shows some selected countries in relation to the Czech Republic.

Table 1 – The tax burden in selected types of taxes. Source: Own elaboration.

	Cyprus	Lithuania	Luxembourg	Malta	The Netherlands	Great Britain
Double Taxation Avoidance Agreement with the Czech Republic	Yes	Yes	Yes	Yes	Yes	Yes
Taxation of capital income	No	No	No	No	Yes	Yes
Taxation of payment of dividends from the Czech Republic	No	No	No	No	No	Yes
VAT rate	8% 15%	21% 9% 5%	3%, 6% 12%, 15%		6% 19%	0% 5% 20%
Income tax rate	10%	15%	21,84%	35%	20-25.5%	30%

### 3.3 Offshore Countries Used in International Tax Planning

Offshore destinations are characterised by the fact that they have a benevolent relation to the entrepreneurial environment. Gains from entrepreneurial activities of a company are not usually taxed at all or only by the minimum in the form of an annual fee for “company operation”. These destinations usually offer absolute anonymity as to the publication of the real owner of income and bank transactions. The table shows some selected countries in relation to the Czech Republic.

Table 2 – The tax burden for selected types of tax. Source: Own development.

	Bahamas	The Virgin Isles	Hong-Kong	Lichtenstein	Panama	The Seychelles
Double Taxation Avoidance Agreement with the Czech Republic	No	No	Yes 2012	No	Yes 2013	No
Taxation of capital income	No	No	No	Yes	No	No
Taxation of income of legal entities	No	No	No	Yes	No	No
Filing the income tax return	No	No	Yes	Yes	No	No
Provision of data about the company	No	No	Yes	No	Yes	No

Companies in countries where the tax return is not filed pay the minimum annual flat rate fee to the state.

The most favourite tax havens in the Czech Republic were the Netherlands, Cyprus and Luxembourg in 2010.

### 3.4 Tax Planning

At the current era of globalised world there are few companies operating exclusively in a single region or a single country. The absolute majority of medium-sized and large economic

entities implement their economic activities in two and more countries, both within the EU, and outside it. Tax planning means using tax-advantageous provisions of laws in individual countries (Široký, 2013).

Tax planning can be performed by:

- Tax optimisation
- Transfer pricing – transfer prices, i.e. the method of profit distribution
- Treaty shopping – an agreement on purchasing
- Double Taxation Avoidance Agreements
- Tax residency, the global tax duty
- Tie-breaker rules within double taxation avoidance agreements
- Permanent plant
- Withholding and security tax – from 1 January 2013 more than double as high increase in the taxation of payments to tax havens in the Czech Republic but this measure does not apply to every tax haven
- CFC legislation – based on the basic principle of avoiding the leakage of tax income abroad, the rules are not implemented in the Czech Republic (Kozák, 2013).

Offshore and onshore enterprising within the international tax planning is not anything else than using the tax-advantageous provisions in the acts of individual countries. The basis for successful enterprising is the reaching of a competitive advantage. Therefore, entrepreneurs in the whole world strive to search for competitive advantages. It needs to be realised that taxation as such is a cost and entrepreneurs can achieve a competitive advantage in the field of international competition especially by means of reducing their costs. It is absolutely legitimate, and even desirable for competitiveness of enterprises, to use these advantages and to efficiently optimise their tax duty. By the correct selection and setting of the given structure, it is possible to significantly reduce the total tax burden down to zero (Mandel and Tomšík, 2011).

Every company has different requirements in tax planning. A location, free trade zones, anonymity and jurisdiction is important for an international trading with goods. Hong-Kong or Cyprus best meet such conditions. Investors that provide their funds for projects by means of loans also engage in developer projects. Interests form a tax-eligible cost and therefore investors seek a location where collections of revenue interest are not taxed. It is suitable to use companies registered in Cyprus and Malta for this type of transactions. Another element of tax planning is anonymity of ownership while preserving the control. International holding structures which meet both the elements of anonymity and ensure high image, tax-exempt sale of ownership interests within the group and tax-exempt flow of dividends serve for such purpose. These conditions are met by jurisdictions of Cyprus, Malta, the Netherlands, and Luxembourg etc. With regard to portfolio investments in publicly tradable securities, standard offshore companies at the Seychelles, Panama and the British Virgin Islands are used. When providing licences, it is important, when selecting a jurisdiction, to proceed according to individual double taxation avoidance agreements which can reduce the tax rate or even completely eliminate it. John Learned Hand, a US federal judge, answered the question whether tax planning is legal as follows: “The legal right of all tax payers to reduce the amount of taxes or avoid them, which means using the means within the scope of law, cannot be contested.”

## 4 ANALYSIS OF FACTORS INFLUENCING DECISION-MAKING OF COMPANIES

Two hypothesis were established prior the analysis:

*H<sub>0</sub> – On the basis of the analysis of all the factors affecting companies' departure to tax haven, we can define that companies' departure to tax havens is not influenced by the state tax policy.*

*H<sub>1</sub> – On the basis of the analysis of all the factors affecting companies' departure to tax haven, we can define that companies' departure to tax havens is influenced by the state tax policy.*

### 4.1 Development of Companies Registered in the Czech Republic

The willingness of entrepreneurs to found new companies grows together with economic recovery. In 2013, 22 845 new companies were founded in the Czech Republic, which is most in the recent three years. The total number of companies exceeded 391 thousand and it increased almost by seven per cent on year-to-year basis. It follows from the analysis of the Bisnode consulting company. In the first half of 2014, 12 557 companies were founded, which was more by 4.43% than in the same period of the previous year. If this trend persists, most companies since the pre-crisis year of 2007 will be established this year as follows from the analysis of the Bisnode consulting company. The total number of companies registered in the Czech Republic exceeds 400 thousand according to the Czech Statistical Office. However, the share of joint-stock companies in the entrepreneurial base has been decreasing. It is also connected with the prohibition of anonymous stock in the Czech Republic.

Table 3 – The number of companies registered in the Czech Republic. Source: Own elaboration.

	2013	2012	2011	2010	2009	2008	2007
Limited liability company	374 514	348 334	332 987	316 429	296 787	280 736	269 763
Joint-stock company	25 057	24 937	24 714	24 042	23 221	22 888	20 455
Total	399 571	373 371	357 701	340 471	320 008	303 624	290 218

According to the Czech Statistical Office as of 31 December 2013, the share of active and inactive joint-stock companies was 84.19% of active ones and 15.81% of inactive ones. The share of active and inactive limited liability companies was 75.11% of active ones and 24.89% of inactive ones.

Figure 1 – The development of the number of companies registered in the Czech Republic. Source: Own development.

Table 4 – The number of newly established companies in the Czech Republic. Source: Own development.

	2013	2012	2011	2010	2009	2008	2007
Limited liability company	22 227	21 592	21 174	22 460	21 756	22 638	21 063
Joint-stock company	618	862	1 159	1 174	1 095	1 336	3 967
Total	22 845	22 454	22 333	23 634	22 851	23 974	25 030

Figure 2 - The development of the number of companies established in the Czech Republic. Source: Own development.

#### 4.2 Departure of Czech Companies to Tax Havens

Entrepreneurs that lose profits due to high taxes use the only possibility how to efficiently express their disagreement with the policy of their country. It is failure to pay or avoidance of payment the taxes, which can be implemented absolutely legally in practice by transferring the registered office of the company to a country with better conditions for doing business, i.e. to a tax haven. In total, in 2010 there was a drop in the interest of Czech companies to transfer the registered office to tax havens, and the year-to-year increase thus only reached 2.5%, which was the lowest year-to-year increment of recent years when ČEKIA monitors these statistics. ČEKIA explains it as follows: “The reason for the decrease in the interest of entrepreneurs in tax havens is connected with the saturation of the market, the continuing difficult economic situation in the Czech Republic as well as with the slight optimism of entrepreneurs after the victory of the right wing in the Parliamentary election or by the pressure of advanced countries, including the Czech Republic, on tax havens and their efforts to conclude agreements on the exchange of information in tax matters.”

Another reason is the protection of anonymity. Since January 2014 bearer shares have been cancelled in the Czech Republic and this resulted in a higher outflow of companies to tax havens.

Table 5 – The number of Czech companies with an owner in a tax haven. Source: Own elaboration.

	2013	2012	2011	2010	2009	2008
Belize	127	118	94	83	77	55
The Virgin Islands	483	455	438	422	424	441
Cyprus	1965	1904	1705	1550	1411	1150
Lichtenstein	248	261	255	245	262	275
Luxembourg	1160	1173	1192	1254	1241	935
The Netherlands	4396	4443	4501	4519	4551	3474

Panama	204	199	190	170	162	108
The Seychelles	590	512	414	330	262	225
The U.S.A.	2867	2903	2750	2630	2545	2135

The total development of the number of Czech companies with an owner in a tax haven is as follows since 2008:

Table 6 – The total number of Czech companies with an owner in a tax haven. Source: Own development.

	2013	2012	2011	2010	2009	2008
Total	12719	12676	12196	11424	11143	8990

### 4.3 Departure of Slovak Companies to Tax Havens

The situation is similar in the other countries of the European Union. For comparison, we provide the table of the number of Slovak companies with an owner in a tax haven.

Table 7 – The number of Slovak companies with an owner in a tax haven. Source: Own development.

	2013	2012	2011	2010
Belize	117	96	75	51
The Virgin Islands	88	78	81	78
Cyprus	755	757	600	535
Lichtenstein	32	28	18	15
Luxembourg	354	392	344	318
The Netherlands	1124	1110	1052	1050
Panama	94	62	38	25
The Seychelles	220	180	65	18
The U.S.A.	859	760	671	601

The total development of the number of Slovak companies with an owner in a tax haven is as follows since 2010:

Table 8 – The total number of Slovak companies with an owner in a tax haven. Source: Own elaboration.

	2013	2012	2011	2010
Total	3853	3646	3093	2830

This series shows that the number of companies with an owner in a tax haven has been increasing even though there is an outflow of companies from some destinations to more advantageous destinations. In Q1 2014 as many as 185 companies has transferred their registered offices from Slovakia to tax havens, while in the previous year it was 208 companies. The departure of Slovak companies to tax havens is especially caused by increasing the taxes and the growth of administrative burden.

It is clear from the development in the Czech Republic and Slovakia that the number of companies with an owner in a tax haven has been increasing.

#### **4.4 Foreign Registered Capital of Czech Companies**

A study dealing with the ratio of foreign registered capital in Czech companies to the foreign capital with an owner from a tax haven follows from the MagnusWeb database. Foreign capital in Czech companies has remained almost at the same level in the range of CZK 920 – 960 billion since 2010, of which foreign registered capital controlled from tax havens has increased from CZK 350 billion to CZK 490 billion since 2010.

#### **4.5 Tax Haven Selection Factors**

Factors typical for tax havens

- Ring fencing – the manner of financing
- Low or zero effective tax rate
- Lack of tax system transparency
- Lack of efficient exchange of information
- Exemption of income from foreign sources

35 countries have been identified as a harmful tax haven and 47 countries have been identified as potentially harmful tax regime.

Five best tax havens with regard to Czech entrepreneurs include:

- The Netherlands, 4 396 Czech companies with a Dutch owner
- The U.S.A., 2 867 Czech companies with a US owner
- Cyprus, 1 965 Czech companies with a Cyprian owner
- Luxembourg, 1 160 Czech companies with a Luxembourgian owner
- The Seychelles, 590 Czech companies with a Seychelles owner

Advantages of founding of these companies include:

- Possibility to reach a zero profit
- Founding a company with no financial costs
- Prestige of a European company
- Higher entrepreneurial freedom
- Low fee replacing the income tax
- No taxation of legal entities

Time exigency of administrative processing as well as simple tax environment which discourages from investments are important for founding a company in a tax haven.

The data were taken from the research within the Doing Business project which compared companies of 185 economies.

Table 9 – Paying taxes – summary. Source: Doing Business Project.

	Number of tax payments per year	Time devoted to taxes	Tax on profit (%)	Wage tax and levies	Other taxes (%)	% of profit
Eastern Asia-Pacific	25	209	16.7	10.9	6.9	34.5

South Asia	30	311	17.1	8.7	14.4	40.2
Sub-Saharan Africa	39	319	19.0	13.3	25.5	57.8

The table shows that OECD countries with high income have the lowest time exigency for administrative processing, while Latin America and the Caribbean region twice as high.

Table 10 – Tax payment in TOP 5 and the Czech Republic. Source: Doing Business Project.

	Value of paid taxes	Number of payments per year	Value of time per year	Tax on profit in %	Wage tax and other levies	Other taxes in %	% of profit
The Czech Republic	120	8	413	7.5	38.4	3.4	49.2
The Netherlands	29	9	127	20.6	18.1	1.3	40.1
The U.S.A.	69	11	175	27.6	10.0	9.0	46.7
Cyprus	31	28	147	9.0	11.8	2.1	23.0
Luxembourg	14	23	59	4.1	15.4	1.5	21.0
The Seychelles	20	27	76	23.3	1.7	0.7	25.7

The research dealt with numerous comparisons of values but it especially focused on the number of tax payments and time exigency of book-keeping and tax processing.

The comparison of TOP 5 tax havens with the

1. The value of collected taxes – the Czech Republic highly exceeds TOP 5
2. The total number of tax payments per year. The indicator shows the total number of paid taxes and contributions, the manner of payment and frequency of payments – the Czech Republic has a significantly lower number of tax payments per year. They include the income tax of legal entities, the value added tax, the road tax, the real estate tax, and the employment tax.
3. Time necessary for the preparation, filing and paying (or refusal to pay) the income tax, value added tax and social security (in hours per year). The table shows that time exigency exceeds TOP 5 as well as the highest values in South America and the Caribbean region.

4. The amount of tax on profit paid out by companies as a percentage of business profit – it is significantly lower in the Czech Republic compared to the Netherlands and the U.S.A.
5. The amount of income tax of employees – the burden of employees is high in the Czech Republic
6. Other taxes – there are different taxes in different state therefore we will not compare them
7. Total tax duty – it is comparable in the Czech Republic with the other TOP 5

#### **4.6 Selection of the Most Advantageous Tax Haven**

There are numerous companies dealing with various activities, trade, services, real estate transfer, trading securities, trading real estate.

International trade – as far as the international trade is concerned, the region of trading, the region of customs warehouses and free trade zones is important for a company. With regard to anonymity of owners and tax optimisation, Great Britain and Malta are suitable in Europe, and the U.S.A. and Hong-Kong in the world.

International services – the same conditions apply in the field of services as in trading the goods. When the setting is correct, the taxation rate is between 1 and 2%. Suitable locations in the EU are Great Britain and Malta, in the world the U.S.A. and Hong-Kong.

Real estate trading – the investor provides its funds for projects by means of loans and interests on such loans. The interest is usually taxed in the Czech Republic with regard to withholding taxes at the place of interest payment source and consequently at the place of revenue interest collection with regard to income tax. Such location in the EU is e.g. Malta.

## **5 SUMMARY OF RESULTS**

Approximately 15% of countries are considered to be tax havens. These countries have a tendency to be small and rich. A statistically significant factor influencing the probability for a tax haven establishment is the quality of state administration. This probability will increase from 26% to 61% in a state with the population below one million together with the growth of state administration quality (Dharmapala and Hines Jr., 2009). The evidence from US companies suggests that low tax rates offer much stronger stimuli for foreign investments if the state is well administered. Due to this reason, the tax policy should be added in the list of economic policies which can be affected by public administration bodies (Nunn and Trefler, 2006). Tax havens are the states with a high quality public administration, political stability, preserving the principles of the legal state, the government efficiency and democracy (Kauffmann et al., 2005).

According to analysis of Czech companies it is evident, that since 2007 the economy is raising and entrepreneur's willingness to start business is growing. The number of newly founded companies is rising. But since 2008 the number of companies with an owner in a tax haven is also rising.

In 2009 the number of companies with an owner in tax haven was 23,95% higher than in 2008. In 2010 the number of companies with an owner in tax haven was only 2,52% higher than in 2009. In 2011 the number of companies with an owner in tax haven was 6,76% higher than in 2010. In 2012 the number of companies with an owner in tax haven was 3,94% higher than in 2011. In 2013 the number of companies with an owner in tax haven was 0,34% higher than in 2012.

The progress is not steady, the departure to tax havens are following changes in governmental tax policy. Lehman Brothers Holding Inc. collapse in 2008 contributed to the high raise we observed in 2009. EU member states adopted tax measures (European Commission, 2010). Those were dominantly discretionary measures to support financial sector and demand revival. The number of companies departing to tax havens rose by 23,95 per cent.

In 2010 the tax burden is shifted from direct taxes to indirect taxes, there is backing of fiscal policy and there is also backing of the measures for lowering of the budget deficit. In 2011 most of the tax measures increase taxes, tax mixture changes, the work tax decreases, there is new taxation of financial sector, benefits, capital market, new ecology taxes are introduced and/or raised. The per cent of departures rises again up to 6,76%.

In accordance with the aforementioned analysis, the  $H_0$  hypothesis (the departure to tax havens is not influenced by states' tax policy) is disproved. Every tax policy change between 2008 and 2013 did influence the companies' departure to tax havens.

To support the conclusion the secondary state of Slovakia was also analysed. In 2011 the number of companies with an owner in tax haven was 9,30% higher than in 2010. In 2012 the number of companies with an owner in tax haven was 17,88% higher than in 2011. In 2013 the number of companies with an owner in tax haven was 5,68% higher than in 2012. This course suggests that the governmental changes of Slovak tax policy lead to the rising numbers of companies departing to tax havens. In 2011 Slovakia introduced new policy for preventing tax evasions.

The survey shows that more than three per cents of Czech companies have their registered office in a tax haven and their number has been increasing. Large as well as smaller companies depart. Numerous entrepreneurs state the reasons such as bureaucracy, instable tax laws, the breach of anonymity etc. Although only three per cents of companies of approximately 400 thousand of the ones registered in the Czech Republic are controlled from tax havens, about 30% of entrepreneurs would change their registered office to a tax haven. The government did not manage to prevent these departures and they still believe that three per cents of companies are few, but while the amount of foreign capital invested in domestic joint-stock companies and limited liability companies dropped on the year-to-year bases, the amount of the capital from destinations considered to be tax havens increased by CZK 69.4 billion on the year-to-year basis, i.e. by more than 17%. The most attractive tax havens of Czech companies include the Netherlands, Cyprus and Luxembourg.

Although the number of companies has been increasing in the Czech Republic, according to the Czech Statistical Office the share of inactive limited liability companies is almost a quarter and the number of inactive joint-stock companies reaches 15%. This statement needs to be considered for the analysis. There is no statistics for newly founded companies whether they transfer their seats to tax havens but according to the survey large enterprises reaching a profit transfer their registered office. The following companies left for tax havens in 2014:

- NET4GAS, s.r.o.
- ENERGOCHEMICA SE
- ARKADIA, a.s.
- Agro Tera,a.s.
- Bea Development, a.s.
- TCCM s.r.o.
- QUARRYHILL s.r.o.
- Global Facility, s.r.o.
- Česká realitní a.s.
- GRAND PRINC MEDIA, a.s.

It is possible to restrict tax avoidance through tax havens especially by improving the work of Tax Offices. Their extension is necessary for this purpose. The work of tax offices in the United States, Germany or France shows it is possible. The current government should create conditions for it. It is possible to act more strictly against tax avoidance through tax havens and off-shore centres. It requires a strong support of the domestic government and the cooperation of the states at the international level. The solution must necessarily include the unification of the tax base amount and the tax rate at least at the level of EU, and introducing a withholding tax on transactions with companies with the registered office in a tax haven.

Recommendations which should make companies conduct business in the Czech Republic include:

1. International exchange of information should be ensured among states
2. This exchange of information should operate without the prior request if the state believes the information in the other state can be useful
3. Setting of such tax conditions which would be advantageous

4. Avoidance of double taxation
5. Distributing the tax revenues between both the states

So far the economy is not affected by companies' departures to tax havens, but the rising numbers (3% of Czech companies have an owner in a tax haven and 17% of Czech companies' capital volume is located to tax havens) are alarming.

## **PHILANTROPY AS PART OF THE REGIONAL CONTEXT FOR SOCIAL INCLUSION**

*Helena Kolibová, Magdalena Chmelařová*

### **Abstract**

The aim of this paper is to analyze corporate philanthropy and description of the situation in the field of philanthropy among target legal entities and individuals operating in the Moravian-Silesian Region. Regional labor market is marked by the passing restructuring and high unemployment.

In order to cover the issue, the analysis of secondary data was carried out (quantitative approach) and credible figures concerning cumulated tax returns submitted in 2014 on donations, total bulk of the donations and the number of entities that submitted the tax return for the year 2013.

The every business activity is put into the context of social culture within cultural patterns. Therefore, we wish to highlight the fact that an inclusive concept of corporate and individual donations bonds is able to contribute to a development of the civil society.

The article was based on the implementation of the project called “*Specialized maps and systems to support seniors and cooperation between participating players for the development of volunteering*” (project number TD020048), which is solved with financial support from TA CR.

*Keywords: Corporate philanthropy, forms of donations, donator motivation, areas of support, corporate social responsibility, stakeholders, tripleAbottom.*

JEL Classification: D14, M14, M15

### **1 SPECIFICS OF PHILANTHROPY**

Philanthropy is not just a one-off donation in order to “do good” and help. It is an activity that promotes the functioning of community life. It stimulates a harmonious environment and arises from a sense of togetherness towards the area of life, work, and living.

The basis of a broader perception of philanthropy in its context is a holistic concept of altruistic behaviour. Thus, the concept of philanthropy forms a unit exceeding more than the summary of its parts, including the ways of their implementation. It is formed by the solidarity of individuals, corporate companies and society-wide solidarity with its stimulating outreach. The philosophical basis for a holistic approach to donations must be based on respect and knowledge of the environment - people, nature, and social orientation. Hence, it reflects a donor’s relation to their neighbourhood in the hierarchy of values and freedom of choice. In this respect, philanthropy belongs to preventive and creative activities affecting society both as ex ante and ex post to solve social problems (Stiglitz, 1986).

The major point of consideration for altruistic behaviour in business environment and its ties to non-profit entities is the attitude to the issue of whether companies are exclusively economic and/or moral entities concurrently (Potůček, 2005). Adopting an attitude on the concept of funds reallocation and redistribution out of a key framework of government intervention signifies a related issue.

According to the author team, the view that society as a whole provides a framework and allows individual entities to achieve their goal, has the general support. In this respect it is possible to understand that every business activity is put into the context of social culture within cultural patterns (habits, customs, laws, and taboos), where their nature has a moral character (Šmajš, Binka, & Rolný, 2012). The moral maturity of business entities has, from this point of view, a direct impact on ties to the community and helps to create the essence of corporate philanthropy. This means that an organization as a bearer of its own contribution and access options to the economic and social reality actively contributes to improving the quality of life. It also strengthens social consensus with the emphasis on maintaining traditions and a regional context.

*The primary objective of the analysis is to answer the following questions:*

*What is the situation in the field of donations in the Moravian-Silesian region for both legal entities and individuals expressed as a percentage share between donations in the target groups and the amount of realized donations?*

*What was the overall average of financial donations provided in the Moravian-Silesian region?*

*What topics is philanthropy connected with?*

### **1.1 Theoretical bases for corporate philanthropy**

Nowadays, there are two basic approaches to corporate philanthropy in the Czech society. We can differentiate between the **reactive concept**, when the company has not any adapted corporate philanthropic strategy and evaluates every single request for donations, and the **proactive concept**, when the company uses a developed philanthropic strategy including the rules and chosen supported target groups or areas; or as an old and new corporate philanthropy (Smith, 2003).

In case of proactive or new philanthropy, effects develop the reason for the altruistic approach because repeated support:

- appears to be much more rewarding due to the fact that it includes a long-term perspective. This allows donated funds to be included into the plans of individual organizations beneficiaries and use the funds efficiently. It complements and diversifies financial resources and helps to create job opportunities in the area,
- gives a clear framework for a donor organizations' policy and thus prevents an excessive number of applicants whose project bears no relation to donor priorities of the company,
- strengthens a benefactor's image; can help to strengthen brand loyalty and presents the strategy of the company openly. Because of its transparency it is a tool for incentive company policy and the way how to work with the public, including embracing principles of the social organization's responsibility.

## **1.2 Donation forms**

In reality, there are two forms of donations (Postoje k problematice dárcovství, 2010).

### **a) Cash donations**

This is the easiest, fastest and also the most commonly used method of support. Alternatives:

- *Direct support* is the most common form. It is based on the fact that the company donates financial or material resources once or repeatedly to support a beneficial community project.
- *Collection among employees and matching fund.* The company or employees themselves organize a collection directly. The collection is often performed on the principle of “matching”, which is based on the fact that the company will increase (e.g. will double) the means collected among employees. This form combines employees’ engagement and corporate support. Especially large foreign statewide companies, operating in services, acquire resources on gifts through a collection among employees. Large international business companies, mostly with a Czech investor, prefer the matching fund as an alternative source of funds for their donor activities.
- *Corporate foundation / corporate endowment fund.* They work as independent legal entities. They differ from other foundations about the fact that their founders are companies which they get most funds for the implementation of long-term charitable programmes from.
- *Charity auctions and exhibitions.* They are organized by a company for employees, business partners, or customers. The resulting financial proceeds are used for charitable purposes.

The support of entities by a financial contribution (a gift) remains the most frequently used form of a support in companies (Peková, Pilný, & Jetmar, 2005). The crucial majority of companies are engaged in cash donation. The form of material donation is represented numerically less, but still strongly (over 50%).

Tax treatment options how to deduct gifts and reduce the tax base are different.

*Individuals* as the donors may, according to the income tax law, deduct the value of a gift from their tax base. But the total value of donations in a given year must be greater than 2% of their tax base, or is at least CZK 1,000. However, it is possible to deduct the maximum of 15% of the tax base (the maximum limit was 10% of the tax base till the end of the year 2013).

*Legal entity* as the donor is entitled to the deductibility if the value of a gift (or all gifts of one organization) is at least CZK 2,000. In the case of a donation, the donor may apply a deductible item and decrease the adjusted tax base. *(In contrast to the individual, legal entity reduces the tax base of the item deductible from the tax base (§ 34 of the ITA) as a tax loss deduction, support of research and development, or deduction for vocational training. The value of the gifts can be applied if they conform to the rules laid down by law. If the donor is subject to VAT and gives a gift, it is necessary to pay VAT based on the value of the gift. Financial donations are not subject to the value added tax. For a donor, the VAT is a further cost associated with the gift).* Even with the legal entities, there is an increase since 2014 and

at the same time the limit for deduction of donations to the maximum of 10% of the tax base is unified.

### **b) Non-monetary donations**

It is gradually becoming a common way how to support charitable activities.

- *Training, education and professional support.* Companies may contribute towards developing expertise and professionalism of non-profit organizations and their cost savings by providing these services free of charge or at a low cost.
- *Providing facilities for the operation of non-profit organizations.* Companies can provide premises, pay rent, lend equipment or distribution network, provide presentations and advertising options (on product packages, in correspondence, etc.).
- *Corporate volunteering.* Generally, it connects beneficial company activities with the support of employee volunteering. The company releases its employees to perform voluntary activities. It also establishes contacts and partnerships with non-profit organizations where the employees can work as volunteers in single events or long-term projects. Corporate volunteers can take part both in purely charitable unskilled works and professional ones. For example, they help to create a PR or marketing plan of a non-profit organization, website, or a computer network. The employees need not take a holiday but they are fully paid by the employer as time worked.
- *Participation on the boards and grant committees of non-profit organizations.* The company representatives bring perspective of professionals from the opposite side to a non-profit organization. At the same time they strengthen credibility of organizations and a public benefit of the activity.

*Connection between the philanthropy and other corporate activities.* It is a specific approach of “doing good” when philanthropic activities are linked with commercial ones (e.g. with the use of marketing tools). It does not only arise from purely altruistic motives, but it depends on the actual corporate attitude (Giving USA 2014 Report Highlights).

- *Cause related marketing (shared marketing).* A company donates a certain amount of one of its selected products for charitable purposes. For example, every crown of a particular product sold goes to the target groups (disabled children, animals’ shelter allowance, the reconstruction of cultural monuments etc.). The contribution of goods sold is frequently used by large statewide business firms with a Czech investor mainly. These activities bring about effects for non-profit organizations in the fact that, in addition to financial income, the public interest in the philanthropic topics is increasing.
- *New products using existing technology.* The company is involved in a formation of facilitating mechanism for supporting community activities, where a non-profit organization is exempt from fees (e.g. Collection account of the Czech savings bank *Česká spořitelna*, or project DMS - Donor SMS).

## **2 SITUATION IN DONATIONS OF INDIVIDUALS AND LEGAL ENTITIES IN THE MORAVIAN-SILESIAN REGION**

The core of philanthropic actions lies in the practical procedures. Their common motto is a development of the civil society not only at the moral level, but financial and material levels at the same time. The Ministry of Finance in the Czech Republic annually draws up aggregate data, concerning donations, derived from filled tax returns of individuals and legal entities. The registered donations are in the range of 4 billion Czech crowns within the last three years.

Various forms and activity tools suit individual participants. Naturally, the degree of their support is also differentiated depending on a different economic base. The Moravian-Silesian region is a difficult area not only in terms of the unemployment rate and its level, but also in the incidence of socially pathological patterns, etc. Therefore, the authors have focused on understanding the situation in the field of philanthropy in the Moravian-Silesian region with two target groups. They are both individuals and legal entities and the focus consists in expressing a percentage share between donations and the amount of realized donations.

The parts of statistical summaries do not contain support topics and target groups of support beneficiaries. It means that observations on what types of gifts or their nature are not realized at this level. It is possible to deduct all the gifts from the tax base that are rendered non-profit organizations and state organizational units, i.e. the police, political parties, health care, education, churches, etc.

The Moravian-Silesian region is a region with problems in heavy industry, unemployment is high, the condition affects the decline in purchasing power. In the region grown regional disparities in quality of life (southwest Frýdek-Místek and northwest areas Opava are in contrast with the eastern area Karviná, Havířov due to the unemployment rate and air quality). The region is the lack of consistency and low flow of information between public and private actors in the field of philanthropy, weak utilization of voluntary cooperation.

### **2.1 Methodology**

Mathematical-statistics methods were used within the research and they are useful for improving the solution of professional problems and tasks. The reason for their choice was the fact that they contribute to the promotion and improvement of a professional decision-making. In order to cover the issue, the analysis of secondary data was carried out (quantitative approach) and credible figures concerning cumulated tax returns submitted in 2014 on donations, total bulk of the donations and the number of entities that submitted the tax return for the year 2013. Furthermore, numerical characteristics of random variables (often called moments) were analyzed and they are divided into three groups. Nonetheless, we requested information, i.e. what was the donation in differentiation between districts with separate legal entities and individuals (*they were mass phenomena which are formed by individual cases. DAP - tax returns, DPFO (PIT) stands for personal income tax*), and we used location characteristics which give the expected value (mean) and distribution. Besides expected value, the median, mode and percentile belong to location characteristics.

When the data files were acquired, the conditions corresponded with unified legislation, which was historically valid, and procedures in key organizations. The results are presented in a structured form of graphical and tabular outputs including comments. Since the authors have worked both with directly observable and derived indicators, conclusions of the research convey the findings which will enable to meet the objectives of the paper together with other information (*directly observable indicators - DAP and PIT, derived indicators – e.g. average*

*gift, aggregate deduction, etc.*). The research subject is rather a corporate donorship, namely its division into individuals and legal entities.

### **Method for selecting a sample of respondents**

The entities of the Moravian-Silesian region as specified statistical units represented a basic information file and were registered at the Tax Office of the Moravian-Silesian region. The Office has provided information based on data in the tax period of 2013 under the Act 106/199 Coll. on Free Access to Information.

Sampling of a statistical unit was defined in terms of:

- Factual aspect – individuals and legal entities who are obliged to provide the information required by law,
- Spatial aspect - the Moravian-Silesian region,
- Temporal aspect - entities that submitted a tax return for the year 2013 in 2014, i.e. on long-term basis.

Namely they are:

Karviná district, regional office Karviná, Bohumín, Český Těšín, Havířov, Orlová.

Ostrava district, regional office Ostrava I, Ostrava II, Ostrava III.

Nový Jičín district, regional office Nový Jičín, Fulnek, Kopřivnice.

Frýdek-Místek district, regional office Frýdek-Místek, Frýdlant nad Ostravicí.

Bruntál district, regional office Bruntál and Krnov.

Opava district, regional office Opava and Hlučín.

The current data provided by the Tax Office have become the starting point for the sampling design.

### **Sample size determination**

Information of individuals and legal entities were included into the sample size selection (*In terms of income tax, donors can be divided into two basic groups. Individuals - ordinary citizen, an employee, or a person who has income from independent activities or rental income, eventually from other activities; Business entity - a legal entity.*). We compared data of the total 186,601 (DAP total) submitted tax returns of individuals, of which 13,444 documents were tax returns with a gift (DAP with a gift). As for legal entities, there were 29,982 (DAP total) submitted tax returns processed, of which 1,830 were tax returns with a gift (DAP with a gift). During the analysis, we statistically worked with a planar set of people with the tax liability under the Act No. 586/1992 Coll. on Income Tax as amended. The abundance of the sample of respondents and the method for their selection ensure representativeness of the results and high degree of validity (tab. 1, 2).

### Structure of the sample of respondents

Tab. 1 – Overview of individuals with tax returns (DAP). Source: Tax Office data, own calculations.

District	DAP total	DAP with a gift	Amount of donations
Bruntál	14,183	764	8,311,637.00
Frydek-Mistek	33,912	2,860	40,226,907.00
Karviná	34,176	2,619	34,776,915.00
Nový Jičín	23,133	1,696	20,476,447.55
Opava	29,306	1,906	21,474,469.00
Ostrava	51,891	3,596	46,337,234.00

Tab. 2 – Overview of legal entities with tax returns. Source: Tax Office data, own calculations.

District	DAP total	DAP with a gift	Amount of donations
Bruntál	1,607	115	5,990,669
Frydek-Mistek	4,950	344	21,395,311
Karviná	3,807	214	9,859,979
Nový Jičín	2,810	198	8,739,218
Opava	3,366	244	7,320,956
Ostrava	13,442	715	33,288,606

### The organization of data collection and validity of the survey

The analysis procedure respected the schedule of tax legislation. That means deadlines of tax returns (the end of June of the calendar year), finalization of tax returns processed in legally responsible organizations, and application of controls. Beside other things, the procedure monitored the elimination of errors caused by human failure. The data passed the entrance and logical controls of Tax Offices.

Fig. 1 – Overview of donating compared to tax returns by regions. Source: Tax Office data, own calculations.

The number of reported donations (figure 1) shows generosity of donors among individuals from the Ostrava district in particular. Although there was a lower than average number of donors, they donated higher amounts distributed to the account of a selected target group, or gave money to classical philanthropic activities, or to newer types of non-profit activities, such as the support for education, the fight against corruption, etc. The lowest level of such activities was performed in the Bruntál district apparently as a consequence of the crisis that hit the numerous poorer sections of the population. It was accompanied by unemployment, debts, or threats by execution processes more than elsewhere (Friedrich, 2006).

The Czechs give annually about CZK 150 per capita to humanitarian donorship (<http://www.nadacevia.cz/cz/radce-darce>). However, it is generally known that persons who submit tax returns are characterized by greater generosity. Usually, the reported amount is over CZK 11,000 a year, although there are significant differences not only between regions, but also between districts.

Particular locations in the Moravian-Silesian region also differ from each other. Data show that the gifts per one tax return were higher in the agglomerations of Frýdek-Místek and Karviná (FM 14,065.35 and KA 13,278.70).

Fig. 2 – FO data overview in the regional context for comparison of the donation per 1 DAP with a gift against 1 DAP. Source: Tax Office data, own calculations.

The results demonstrate a certain reticence of individuals towards donation in the Bruntál district, which reflects the socio-economic situation.

## 2.2 Summary – the main findings

The data show that promoting corporate philanthropy occurs above-average in the Opava district with 7.25% and oddly enough in the Bruntál district with 7.16%. Nonetheless, the level of funds for charity is below the regional average and “financially lagging” behind other areas of the region (graph 2). The involvement of companies, i.e. the percentage of DAP with a gift, in the Bruntál district even exceeds the most outstanding support of financially supporting companies in the Frýdek-Místek district. This is even more pronounced in the Ostrava district with 5.32% and in the Karviná district with 5.62%.

It must be acknowledged that the actual amount of money donated in the region, whether for regional use or solving social and international projects, may be even higher. Donations realized directly in the streets are still present. They are, for example, groups of carol singers in the collection of Three Kings’ Day, World Cancer Day, etc.

The use of new technologies is becoming popular in the Moravian-Silesian region. They are, for example, on-line donations and donor SMS mainly; peer to peer donations based on the principle “from buddy to buddy”; or on-line long-term benefits. Funds for charity arise both from individuals and corporate donors within the Czech society. Currently, an interesting trend called new philanthropy is promoted in the society. On the one hand the loss of donations from companies is recorded but on the other hand they are establishing their own foundations for this purpose. Thus the number of donors from private individuals is

strengthened in practice. Nevertheless, it should be noted that the average donation from individuals differs from the one of legal entities. In the Czech Republic, it is roughly CZK 11,000 per year with individuals and about CZK 132,000 per year with legal entities (*according to data from the VIA Foundation*).

Individual companies professionally compare with each other the amount of charity funds. The differences are not as significant as the differences from a regional perspective. Basically, we can state that professionally they are at the same level, although they differ in themes, timing, or profile of their charity. Distinctions occur in interdisciplinary differences and, of course, between regions.

The average donation from a legal entity amounts to about CZK 132,000. The corporate donations in the agglomeration of Frýdek-Místek have the highest value (CZK 62,195.67), followed by the agglomerations of Karviná (CZK 46,074.67) and Ostrava (CZK 46,557.49).

The companies in the Moravian-Silesian region have undoubtedly an important position within the Czech Republic. These are mainly large organizations and leaders of heavy industry. It is apparent from their placement in the rankings of the association “Czech Top 100”. Since 1994, its main objective has been to compile and publish an annual list of one hundred most important companies in the Czech Republic by selected economic indicators. Two dozen companies from the Moravian-Silesian region are placed regularly in these annual reports (Janoušková, & Sobotovičová, 2013).

In connection with the economic crisis, an income inequality gap shows a “scissors” patterns also in the regional context. It means that due to this fact, opinions of entities and companies on social, group, and personal solidarity began to crystallize. Manifestations of altruistic behaviour began to differentiate mainly towards motivation of their beneficiaries. Not only a number of general studies (*for example, CVVM surveys, Nationwide research on corporate philanthropy was realized in June 2004 by Czech Donors Forum in cooperation with AGNES and supported by the PHARE program - Long-term sustainability of civil society, and VIA Foundation <http://www.nadacevia.cz/cz/radce-darce>*), but also our research shows that feelings of mutual trust and solidarity were reduced by worries about coping with own economic situation and maintaining personal financial security. At the same time the public asked the government to observe control functions and do not squander. In other words, social policy and the concept of a welfare state should be targeted and transparent.

Fig. 3 – Tax records overview of legal entities and individuals. Source: Tax Office data, own calculations.

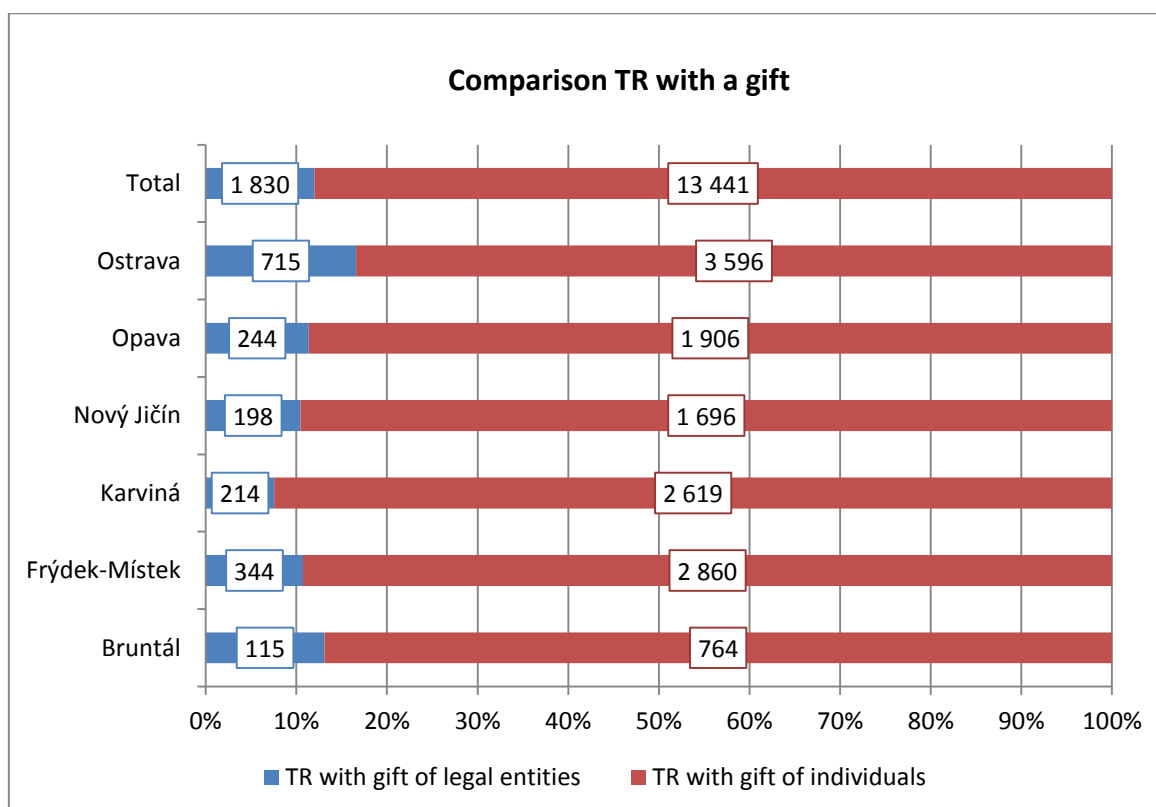

Fig. 4 – Tax records with a gift overview of legal entities and individuals. Source: Tax Office data, own calculations.

The biggest difference of applied tax deductions occurs in Ostrava, Karviná and Frýdek-Místek, where donors within the ranks of individuals ultimately prevail (in thousands) (graph 3, 4).

Private donations in the Moravian-Silesian region exceeded the limit of CZK 171,603,609 in 2013, while corporate donors gave to a “good thing” CZK 86,594,739. Nonetheless, in real terms the growth of individual donations was reduced by inflation, which amounted to 1.4 in 2013 (<https://www.czso.cz/csu/czso/domov>).

Basically, we can say that smaller sums of money from a multitude of donors bring in substantial revenues for much-needed activities and they are a real source of donating.

Fig. 5 – Total donations overview in tax returns, data for 2013 in the Moravian-Silesian region. Source: Tax Office data, own calculations.

### 2.3 The potential for corporate philanthropy in the Moravian-Silesian region

We can conclude that recent years have led to variations in a hierarchy and acceptance of post-materialistic values in a regional environment. In particular, difficult areas in the Moravian-Silesian region still exist (Kolibová, a kol. 2013). The loss of primary public pressure on environmental protection or companies’ compliance with the requirements of corporate social responsibility was somehow demonstrated. But philanthropy and an interest in the possibility of providing tax allowance for making a donation to charity suggest an increasing trend (graph 5) (*An increasing number of donors are showing an interest in the activities of the supported organization and they are insisting on a greater donation transparency.*).

*Identifying trends in corporate philanthropy*

- People with a good standard of living and thriving businesses have remained in their attitudes and support of philanthropic acts. However, it is true that people with declining living standards (i.e. also people close to the median wage which is getting closer to the poverty line) and companies with existential problems are in their attitudes rather radical.
- Companies, which were engaged in philanthropic activities during the last five years, do not plan to increase the amount of donations.
- Reflections on increasing the proportion of corporate philanthropy must take into consideration the fact that the potential for attracting new donors could relate to unconcerned companies, alternatively new legal entities. This might be possible due to the increasing economic companies' performance and the arrival of new investors in the region who utilize industrial zones, for example.
- In the following years, qualitative development of corporate philanthropy may be expected in the areas of cooperation between companies on common projects and in the area of increasing corporate professionalism. It means that large companies, like in other countries, will not make decisions on the selection of a target group or organization only at the level of the management in case of philanthropy. However, they will exploit employee committees to a larger extent and will respect the opinion of the employees.
- Qualitative development of corporate philanthropy refers to the use of various forms and tools of new technologies such as on-line donations, peer to peer donation etc.
- The transformation also refers to guaranteed long-term effects of philanthropy. Companies begin to prioritize their support for competencies, namely donations to a process of education, quality of life, etc.
- In connection with trends in corporate philanthropy and fundraising professionalism, the income of non-profit organizations is growing. These have a strong and sophisticated marketing based on a good reputation.
- Qualitative development of corporate philanthropy will present business decisions of a company. It will focus on public interest of a site as an associated economic benefit.

### **3 CONCLUSION - PHILANTHROPY AS PART OF SOCIAL INCLUSION**

From the given point of view, we can consider altruistic behaviour of individuals and legal entities to be a tool that can be used for the benefit of a broader inclusion strategy in the society (Marion, 2002). However, it should be emphasized that the inclusive concept of relationships between corporate and individual donations contributes to a development of the civil society. Yet, it cannot do without mutual respect and cooperation (CCS's 2014 Snapshot of Today's Philanthropic Landscape Executive Summary).

The degree of positive effects is manifested in regard to the fact whether the particular philanthropic activities represent a comprehensive transformation, or it is a support in the short-term interval (for one-off projects). Alternatively, they can represent systematic long-

term measures, which are capable of stimulating the target group and improving their position either on the labour market or within the quality of life (Janoušková & Sobotovičová, 2013).

The boom of the interest in philanthropy, both corporate and individual, and its use for NGO activities in particular is part of the political support. It is respected even by regional authorities because altruistic behaviour plays an important role and has significance within the Moravian-Silesian region. Donorship, both individual and corporate, has been on the rise after the political changes in 1989. This fact is supported with the CSO data and conducted surveys (<http://www.nadacesirius.cz/soubory/ke-stazeni/postoje-cechu-k-darcovstvi-pruzkum-median.pdf>).

The common denominator of awards and competitions for philanthropists (responsible businesses and donors) is:

- Public expression of thanks as beneficiaries' initiative to the nomination of donors. It is a feedback of solidarity donation which is usually in the form of a moral award and tries to reward and highlight the greatest benefactors or donations as such,
- Publicity and emphasis on the importance of charitable work through competitions and rankings. This is also an impulse for motivation among other individuals and legal entities (*For example, at the beginning of the process of public expression of thanks, there was the award "D" firstly awarded in 2001. Dozen of companies, from individuals to large companies, have been awarded the prize since then. One of the prize-winnings in the national category was Alena Bujáková in 2014, who represented the company Inforpres, and she was awarded for the support of children's home in Frýdek-Místek. Or in 2012, Primary School T.G.Masaryk in Opava was awarded for their support of people in need. Furthermore, the show "TOP Responsible Company" honours only companies that have evaluated their strategy in the field of responsible entrepreneurship and implemented innovative approaches. The ranking is part of the professional corporate platform called Business for Society. Similarly, the price Via Bona is awarded by the Via Foundation.*).

It is necessary to find a balance between needs, possibilities, and solidarity in the relationship between a donor and recipient (Inglehart, 1990) A correct rhythm of altruistic behaviour reinforces the feeling of importance, togetherness, and openness in the emotional level, which is given by a personal relationship to a target group or place. Consequently, it draws a donor into life both at a spiritual level, which is a tribute and expression of relationships sophistication, and physical level, which takes the form of instrumental and financial assistance or a gift, and tax legislation in the society.

## **THE PROPOSAL OF USING ECO-CONTROLLING TOOLS AT THE MUNICIPAL LEVEL IN THE CZECH REPUBLIC**

*Karel Kolman, Eliška Pastuszková*

### **Abstract**

The principles of environmental management accounting have been known for twenty years; this method has been developed for use in the private sector. The process can be applied to public sector organizations whose leaders want to engage the question of environmental impacts in their management, decision-making and control efforts. The aim of this paper is to analyze the usability of environmental management accounting tools for the needs of municipalities in the Czech Republic, and based on the findings, to suggest possible practical applications. Mainly observed is the impact on improving the financial management of the municipality. The possibility of using environmental management accounting tools is based on a questionnaire survey, and then on the basis of the five modules, a functional model of environmental management accounting is created for a specific municipality. Additionally, practical improvements are introduced in the environmental performance of an organization, including appropriate communication with internal and external stakeholders.

*Keywords: Environmental management accounting, municipality, environmental management, EMAS*

JEL Classification: H83, Q56, R51

### **1 INTRODUCTION**

Today, a large number of organizations and individuals are involved somehow in environmental protection. Their efforts mainly concentrate on the area of ex post, which is the practice of disposing of already existing environmental burdens. It is preferable however to prevent these negative effects in the first place. For this reason, environmental management is discussed, which focuses on waste prevention, more efficient use of natural resources, emissions reductions, etc. In practice, there are a number of offshoots of management tools. Their creation, development and use are rooted in the German-speaking part of Europe. Authors brought certain simplification (or rather association) back in the 1990s under the term environmental management accounting (EMA) (Sturm & Müller, 2000). As the title suggests, it is an environmentally oriented application of controlling. This term thus represents the entire control process of decision-making, planning, implementation, monitoring and feedback. The concept, as already mentioned, is used mainly in Germany, Austria and Switzerland for the needs of manufacturing companies.

The authors of this paper explore the issue of usability of environmental management accounting tools, specifically for the needs of municipalities in the Czech Republic. The essence of this effort is the assumption that the vast majority of Czech municipalities neither applies nor even knows about these environmental management tools, or does not approach environmental management conceptually even in terms of its own management and decision-making.

## **2 THEORETICAL BASIS**

Today, businesses are primarily managed economically. Their existence is dominated by financial metrics. Effects resulting from production and product life cycles are ignored. The impact of production on the environment is played down in favor of economic (financial) results for the entire production process. Companies perceive the orientation of the environmental aspect as unnecessary, burdensome or a losing endeavor. Many find it unnecessary to develop activities outside those required by environmental legislation.

Efforts to eliminate the impact of production on the environment are not the only type of environmental behavior. It pays to implement environmental thinking already in the planning and management phase from the very beginning of the production process as a strategic management tool (Naan & Horst, 2011).

Managerial environmental management accounting is based on the fundamental processes of financial controlling. It assumes a strategic approach to environmental issues and proposes a systematic approach with various management steps starting with strategy formulation, decision support, management, implementation, and continuing on to communication and control. This concept is based on linking environmental strategy with strategic and financial objectives of the top management of the company. Emphasis is placed on increasing eco-efficiency, defined as the ratio between the impact on the environment (the environmental impact incurred) and value added. Applied in practice is e.g. the contribution ratio (potential) to global warming in relation to a unit of turnover, in proportion to the return on net assets. (Sturm & Müller, 2000)

Successful development of environmental management accounting depends on the organizational, technical and technological conditions and success factors. Environmental management accounting is a topic that transcends departments and hierarchical levels of society. These features make it suitable for all employees and require their involvement as an important success factor. (Neuhaus, 2008)

Environmental management accounting is used as a strategic tool for the effective protection of the environment. It was initially applied predominantly in the German speaking countries of Austria, Germany and Switzerland. Its use is oriented towards manufacturing companies. The concept then spread beyond European countries. One example might be a study conducted on Canadian companies (Henri & Journeault, 2010), which points to the fact that environmental management accounting indirectly affects the economic performance of an organization. Expansion has been going on recently not only in terms of territory but also its specialization. The concept is already used by small and medium-sized enterprises in the service sector and public administration. (Hyršlová & Brožková, 2003)

The content of the concept of environmental management accounting, presented by authors Sturm and Müller, is not particularly specified. Only the general theoretical level is described, consisting of five basic modules (Sturm & Müller, 2000):

1. Determining an environmental policy and aims
2. Information system and environmental accounting (data management)
3. System for decision-making support
4. Implementation
5. Communication

Because this concept is not precisely defined, it provides the opportunity to connect to other existing methods of environmental management and compile them into the five presented modules. One of the basic pillars of the concept is environmental accounting. This type of

management (sometimes rather cost) accounting is used to express the environmental costs and benefits arising from the activities forming an environmental impact. Even in terms of environmental accounting, specific instructions at the level of companies and organizations do not exist. This is due to the fact that the very concept of environmental accounting expects each organization to take an original approach to elaborating environmental costs and schedules. Most publications are based on the work of the authors Sturm and Müller (2000) or Schaltegger (2002), and in the Czech Republic, Hyršlová and Vaněček (2002).

The second pillar, which brings some standardization of the whole implementation process of "eco-thinking", is the program of environmental management and audit system – EMAS for short. This is a "set of rules" above the legal framework with which organizations comply voluntarily in order to improve their environmental performance. The essential attribute of EMAS is the existence of external benefits such as an increase in credibility or better position in the public procurement system (Michelsen & de Boer, 2009; Preuss, 2009). EMAS is currently designed for business and more. Studies were conducted on the implementation of environmental management using an EMAS scheme in Italian cities (Marazzi, Bandini, & Contin, 2010; Mazzi, Mason, Mason, & Scipioni, 2012) EMAS is sometimes compared to similar systems of ISO certification, namely ISO 14001 - Environmental Management Systems (Lozano & Vallés, 2007). The ISO system is the basic level, for which EMAS acts as a certain superstructure. The two approaches have both commonalities and differences. In the Czech Republic, there is also the concept of Green Procurement, which helps institutions financed from public funds to foster environmentally friendly operation. (Síť ekologických poraden, 2015)

### **3 AIM AND METHODOLOGY**

The aim of this paper is to analyze the usability of the environmental management accounting tool for the needs of Czech municipalities; its findings suggest practical utilization, where one may primarily observe the impact on improving the financial management of the municipality.

The research itself included exploring the possibility of using environmental management accounting tools supported by a questionnaire survey on a sample of municipalities. The survey focused on ascertaining the current information base and the needs of municipalities in the environmental field. The sample included all municipalities within the district of Zlín, so the total sample amounted to 89 potential respondents.

The outcomes of this quantitative survey were taken into account in the application part of drafting a proposal for practical use of the concept of environmental management accounting in Czech municipalities. On the basis of the five modules formulated in the works of Sturm and Müller (2000), a functional environmental management accounting model was created for a specific municipality in the Czech Republic. Possible practical steps are also presented for improving the environmental profile of the organization.

A general framework of environmental management accounting was created based on a critical literature review.

### **4 RESULTS**

The analysis involved a survey by questionnaire of selected municipalities, aimed at determining the current information base and the needs of municipalities in the environmental field. All municipalities in the district of Zlín were used for a quantitative survey, totaling in 89 potential respondents. Standardized questionnaires were sent electronically to the e-mail addresses of municipal representatives and collected through GOOGLE Disk. The survey was

conducted April 8-16, 2014, and the return exceeded 25 %. As revealed in the questionnaires and by the authors' investigations, municipalities do not have enough information and knowledge in the field of environmental management. Their attention focused primarily on waste management, recycling and care of public greenery, but without conceptual links to environmental management. Related to this is the fact that awareness among municipality representatives on the use of existing concepts (especially EMAS) is minimal. The survey showed, however, that in the context of the actual functioning of the municipal authority, municipalities strive to behave responsibly. These assumptions may act as a stepping stone for implementing the concept EMAS, ISO 14001 or another concept of "Green Procurement".

#### **4.1 The use of environmental management accounting in Czech municipalities**

For the purposes of practical use of environmental management accounting, it is necessary to rely on the already functioning environmental programs and approaches. The key pillar of the proposed solutions therefore involves systems such as EMAS, Green Procurement and environmental accounting. Based on these instruments, the original modules of environmental management accounting were expanded to include a practical dimension of usability in Czech municipalities.

Modules of environmental management accounting defined by Sturm and Müller (2000) can be defined as follows for the needs of Czech municipalities:

##### **MODULE 1 – Determining an environmental policy and objectives**

Determining an environmental policy and calculation of the environmental footprint of the municipality (municipal authority)

##### **MODULE 2 - Information system and data management**

Quantifying environmental costs and revenues, including an environmental accounting report

##### **MODULE 3 – Decision-making support system**

Description of a simplified EMAS system in combination with elements of Green Procurement, subsidy policy options

##### **MODULE 4 - Implementation**

Practical implementation of a Green Procurement model, evaluation of municipal investment projects in relation to the environment

##### **MODULE 5 - Communications**

Establishing rules and obligations for employees, information for external entities (simplified environmental statement)

These modules are presented in a practical example of a municipality. The municipality Spytihněv was selected as the model municipality. This municipality of the Zlín district has 1,720 inhabitants. Spytihněv has not yet implemented environmental management techniques; on the other hand, it declares its interest in protecting the environment at least through the consumption of materials and energy.

#### **4.2 MODULE 1 - Determining an environmental policy and objectives**

The environmental policy of the municipality in question comes from their statement in which they are declared basic objectives of environmental protection. The main objectives of the municipal environmental policy include:

- Comply with all applicable legislation, standards, rules and regulations on environmental protection and Green Procurement
- Conserve natural resources by reducing the consumption of energy and water, by waste sorting and recycling, and by reducing fuel consumption
- Raising environmental awareness of all employees, influencing their suppliers and customers. Ensure their continuing education and encourage them to protect the environment
- Adhere to the principles of Green Procurement, which represents selection of goods having the lowest possible impact on the environment. Particular keys include energy intensity of production, recyclability and degradability, transport distance and content of toxic substances. When acquiring new office equipment, ensure reduced energy consumption, low emissions and low radiation
- In the process of awarding new projects, ensure an environmental profile of applicants, reducing energy consumption, investment
- Commit tenants of residential and commercial space to ecological behavior, waste sorting, green shopping
- Regularly evaluate the meeting of targets, including ensuring public awareness. Place emphasis on prevention and education in the field of environmental education.

As a support tool for determining environmental targets, it is possible to calculate the municipality's environmental footprint and consider it in relation to the ecological capacity of the territory. This was the means by which data on the monitored municipality was calculated.

#### **4.3 MODULE 2 - Information system and environmental accounting (data management)**

Module 2 contains the setup of the information system and compilation of reports on environmental accounting for the given entity. The following table (Tab. 1) shows a model report of environmental costs and revenues of the monitored municipality of Sptyihněv in 2013.

In the case of costs, the following variables affect four basic areas:

- Waste management, wastewater and air emissions
- Caring for the environment and pollution prevention
- The material cost of non-product output
- Cost of product output.

Tab. 1 - Report on environmental costs and revenues of the municipality Spytihněv. Source: authors' own processing based on financial statements of the municipality

Categories of environmental costs and revenues	The Environmental Domain				
	Air emissions	Waste water	Waste	Other	Total
<b>1. Waste, waste water and air emissions</b>	<b>119 817,00 CZK</b>	<b>831 077,57 CZK</b>	<b>1 004 709,24 CZK</b>	<b>1 948 648,00 CZK</b>	<b>3 904 251,81 CZK</b>
1.1 Depreciation for waste, waste water and air emissions					- CZK
1.2 Equipment maintenance, operating materials and equipment-related services		316 734,00 CZK		1 948 648,00 CZK	2 265 382,00 CZK

The municipality in question only works with outputs from financial accounting records and waste management. For the purposes of management - environmental – accounting, this data is insufficient. The first step, which does not involve any financial burden, is therefore appropriate extension of the chart of accounts to include an analytical breakdown that helped to quickly and uniquely identify environmental financial flows.

#### 4.4 MODULE 3 - Decision-making support system

In the Czech Republic, there are several voluntary environmental tools that can be implemented by public entities in their management in order to improve their environmental performance and position. Therefore, the role of environmental management is to decide which one is suitable for the given organization.

The EMAS scheme seems to be the most advanced instrument (in the current version of EMAS III, see European Commission, 2015). To a certain extent, it is a substitute for its competitor ISO 14 001. Green Procurement evolved in 1996, (zeleneuradovani.cz, 2014), and can also be understood as a certain part (or auxiliary element) of implementing EMAS.

The EMAS concept is a European platform, hence its establishment applies not only Czech but also European legislation (specifically the European Parliament and Council Regulation (EC) No. 761/2001 on the voluntary participation of organisations in a Community eco-management and audit scheme (EMAS III). As is also apparent from the survey of this paper, the majority of small municipalities (also due to certain financial administrative demands) is not familiar with this concept and is not considering its implementation.

Although there are Czech municipalities that have successfully implemented the concept EMAS III (Chrudim and Jilemnice), we selected for our chosen municipality the concept of Green Procurement, which, due to the size of municipality, was less demanding in terms of implementation. On the other hand, it should be noted that as opposed to the acclaimed EMAS, it obviously holds lesser prestige.

The initial state of the municipality was evaluated in the preliminary audit of the concept of Green Procurement. A substantial part of the materials for audit is designed as a form in which it is possible to select from the options yes / no / I do not know. The result of eight major areas is the finding that the areas of water management and interior furnishings warrant the most attention. Here many replied “no” or “I do not know”. Contrarily, the municipality is strongest in the area of heating and heat savings.

#### **4.5 MODULE 4 - Implementation**

Introducing environmental management accounting involved practical implementation of the concept of Green Procurement in the observed municipality. The second part was to create an overview of investment projects of the selected municipality impacting the environment. Based on an initial audit, ten priority areas were selected where there is room for implementing environmental improvements and savings.

Fig. 1 - Priority areas identified in the selected municipality. Source: authors' own elaboration

For each domain, the current situation was assessed and possible solutions were suggested that might bring environmental savings. One example may be the domain of lighting, where savings are evident from the following table.

City Hall offices are equipped with suspended fluorescent lights. Common areas, corridors, toilets, are equipped with conventional bulbs. For simplicity, the assumption is that all the lights are on full-time (i.e. 42 hours per week).

Tab. 2 - Implementation - Lighting. Source: authors' own elaboration

	Type of action	Group	Type	ANNUAL SAVING /ADDITIONAL COSTS		
				Unit	price per unit	CZK
<b>3. LIGHTING</b>	Current situation	fluorescent tube	tube 58 W	8,00	463 CZK	3 706 CZK
		light bulbs	bulbs 60 W	4,00	479 CZK	1 917 CZK
			bulbs 40 W	6,00	319 CZK	1 917 CZK
<b>TOTAL</b>						<b>7 539 CZK</b>
<b>3. LIGHTING</b>	Proposal for improvement / savings	replacement of fluorescent lamps: Philips MASTER TL-D 18W / 830		8,00	42 CZK	⊗ 336 CZK
		<b>(-) savings 40 W</b>		-8,00	319 CZK	⊙ -2 556 CZK
		replacement of light bulbs: olight 4x T3, 540lm, E14, 2700K, 11 W		10,00	36 CZK	⊗ 360 CZK
		<b>(-) savings 49 W</b>		-4,00	391 CZK	⊙ -1 565 CZK
		<b>(-) savings 29 W</b>		-6,00	232 CZK	⊙ -1 390 CZK
		switching off during the day 18 W		-8,00	144 CZK	⊙ -1 150 CZK
		switching off during the day 11W		-10,00	88 CZK	⊙ -879 CZK
		<b>Total of switching off</b>		50%		⊙ -1 014 CZK
<b>TOTAL</b>						<b>⊙ -5 829 CZK</b>

If quantified savings of all specified domains were implemented, it would be possible to manage the office with savings of nearly CZK 30,000 per year. Since 2013, projects have been implemented whose total value exceeds CZK 6,025,000. Currently there are four more prepared projects totaling CZK 13,153,964. All these projects focus on effective environmental protection, waste management, and energy savings or reduced dust.

Purchased materials, refreshments and amenities of the municipality appear wasteful and hint to a lack of an overall concept. Another area that is not fully controlled efficiently is the operation of its municipal service vehicles. Based on these facts, a simple form was created based on a Microsoft Excel spreadsheet containing the following areas:

- **E-shopping** – here employees can enter their requirements for the purchase of materials, goods, equipment, furniture, etc.
- **E-idea** - in this list, users can upload their ideas for improvements and savings in operating the office and in the environment
- **E-ride** - this part is used for ordering service vehicles. The aim is to increase the utilization of individual travelled routes of vehicles
- **E-projects** - describes municipal projects with ties to the environment. Serves to raise awareness among individual employees
- **E-obligations** - Here are listed the responsibilities of individual employees for partial implementation of environmental management objectives.

This document is shared to a shared data repository so that all managers have access to it and are able to track the status of their orders. Selected employees may approve and revise individual requirements. The aim is to centralize a purchasing system so that the principles of green procurement could be respected, to collect insights of employees on possible savings, to raise awareness among all employees and to better organize the operation of service vehicles.

#### **4.6 MODULE 5 - Communications**

For each implementation of a management system, participation is necessary of all interested parties. Environmental management is no exception. It is important to provide information on two levels, i.e. inside the office and in its surroundings.

At the beginning of the process, it is necessary to convince management about the suitability of the tool and effects arising from implementation. The next step is to convince all employees to the extent that they are willing to voluntarily change their habits and adapt to the new environmental management system. Furthermore, it is necessary to put together the schedule of the entire implementation so that all employees know what phase they are now in and what phase awaits them.

The next step is to determine responsibility for the implementation of each task for employees (or unions, departments, etc.). For successful personnel management, responsibilities should be supplemented by motivation and reward for individual employees. Of course there must be regular training in EEA (Environmental education and awareness).

It is also necessary to communicate with external entities. The behavior of public authorities should reflect the motto *Verba docent, exempla trahunt*. (Words instruct, illustrations lead). For this reason, it is appropriate for the municipality to express its environmental efforts to external entities.

The surrounding of the municipality authority can be divided simply into five segments: citizens as the authority's "clients", suppliers, customers and tenants, other public administration institutions and the media.

Methods of communication with these interest groups vary. The first impulse may be a visit to the municipal authority, where citizens can read about the introduction of environmental management (bulletin boards, information panels, gifts, brochures, etc.). Another option is to use the municipal Website, municipal periodicals or an info channel.

An outcome of the concepts EMAS and of Green Procurement is an annual environmental assessment report, in which the municipality assesses fulfillment of environmental policy objectives for the given period. Its achievements are also outlined here, but so is the unfulfilled measure of environmental management accounting.

## **5 DISCUSSION**

As also confirmed by questionnaire survey, selected municipalities resolve the problem of effective environmental protection, but only by partial measures. They lack a comprehensive view of this issue, from the strategic level down to the operational level. Comprehensive tools include e.g. implementation of an environmental management system and an audit of the scheme EMAS III or ISO 14001. However, municipalities are not so keen on implementing such complex measures, or do not even know about these options. The difficulty in implementing these instruments is a basic disadvantage primarily for small municipalities. Embracing environmental management accounting with its variability may therefore be a suitable conceptual tool even for those municipalities not daring to introduce EMAS III and ISO 14001. They can "put together" their own concept into individual modules, which however will eliminate the basic problem with the existing municipalities in the Czech Republic, i.e. the lack of a concept in environmental management and decision-making, and their limitation to partial, unrelated steps. However, for environmental management accounting as well, the main factor remains the willingness of representatives (or citizens) of the municipality to implement a comprehensive concept of environmental management and decision-making.

## **6 CONCLUSION**

The aim of this paper is to analyze the usability of the tool of environmental management accounting for the needs of municipalities in the Czech Republic, and based on the findings, to suggest possible practical applications.

There are some environmental management tools applied in the Czech Republic, the most important of which are the concept EMAS and ISO 14 001. Both of these tools however are mainly used by business entities. Only four public administration entities have incorporated the EMAS concept in their management (two of which are the aforementioned cities). The reason for the marginal involvement of local authorities is a low level of awareness regarding the possibilities of implementation, which is evident from the survey taken among the municipalities of the district Zlín. Potential applicants may also be discouraged by the financial and administrative burden of the whole process, because from the environmental review phase to the final environmental validation and certification, they cannot avoid external entities. The Czech Environmental Information Agency and the Ministry of Environment can offer consultation and assistance. In recent years, it has been possible for implementation to apply for a grant from Czech-Swiss funds and a revolving fund of the ME. Green Procurement can be implemented as an alternative to the EMAS concept as a simpler tool for organizations. The indisputable advantage is simpler applications for small communities, and its disadvantage is lower credibility and less developed reputation.

For these reasons, to create a functional model for environmental management accounting, elements from both concepts were selected, i.e. EMAS and Green Procurement. According to the basic template layout of environmental management accounting, objectives were divided into five modules. The main part (MODULE 4) represents the implementation of environmental improvements and savings in data from a specific municipality. It is simply clear that the introduction of the environmental management accounting tool can reduce the cost of operations of the institution and energy consumption in general. Within the framework of implementation, ten priority areas were selected in which there is room for improvement. Furthermore, a document for information sharing, centralized purchasing organization and operation of company vehicles was created.

The outcome from the survey confirmed the assumption that municipalities in the Czech Republic do not use or do not know of environmental management tools.

## **CUSTOMERS' SATISFACTION AS AN INFLUENCE OF CORPORATE SOCIAL RESPONSIBILITY IN COMMERCIAL BANKS: CASE FROM KENYA AND CZECH REPUBLIC**

*Felix Kombo, Jiří Paulík*

### **Abstract**

Customer satisfaction is a key measure of provision of quality services to clients. Many banks are now focused on ensuring maximum customer satisfaction to their clients as an edge over their competitors for gaining competitive advantage. The actions and initiatives of Corporate Social Responsibility (CSR) influence customer satisfaction though through different levels for each customer. As a result of CSR activities and initiatives, many businesses have been able to retain customers (through customer loyalty), command high profits and high market shares.

The purpose of this article is to investigate satisfaction of Kenyanbank customers. Descriptive analysis is used to analyze our data. The outcomes of our research are entirely based on research results and use of a questionnaire. Based on the results, overall level of satisfaction in Kenya is slightly above Czech Republic. The main reasons for satisfaction in both countries are different while the main reason for dissatisfaction is the same.

**Keywords:** *Customersatisfaction, commercial banks, corporate social responsibility, Czech Republic, Kenya*

**JEL Classification:** G 21, M 31

### **1 INTRODUCTION**

Commercial banks are among the important institutions in any economy in the world. This statement is also reiterated by Sharma and Kumar (2013) who state that commercial banks occupy a crucial role in the development efforts as well as act as catalysts for economic growth. Beck et al. (2010) mention financial development as one of the key development role for commercial banks. The recent financial crisis demonstrated the role of commercial banks and their irresponsible behavior that caused the downturn of global economy. According to Soana (2011), banks played a major role in the financial crisis. Commercial banks have attempted to reclaim their damaged reputation and trustworthiness among others by implementing socially responsible principles within the CSR concept into their strategies. Due to business specifications of commercial banks and their operations with customers' deposits, they have been exposed to permanent public spotlight. Customers are eager to know that transactions with their deposits are transparent and banks behave ethical and avoid frauds committed on customers.

There is the need for commercial banks to ensure that their clients enjoy their services and products by creating lasting customer experience. According to Belás and Homolka (2013), customer satisfaction in banks present an important area of building long-term relationships with clients. Satisfied customers are always willing to buy bank's products and also willing to pay higher prices for products and services (Belás, 2005). For this article, definition by Chakrabarty (2006) has been used in support of Belás and Homolka (2013). Customer satisfaction is how a product or service surpasses customer expectation (Chakrabarty, 2006).

A product or service can only surpass customer expectation if it is of quality. This also leads to customer loyalty. According to Belás, Burianová, Cipovová, & Červenka (2013), customer satisfaction and loyalty are partial activities of CSR.

Luo and Bhattacharya (2006) argue that a firm's CSR initiatives usually lead to better customer satisfaction. They mention that antecedents such as perceived value increase customer satisfaction. Therefore, customers usually derive higher level of satisfaction from products or services that come from companies that are socially responsible. This explains why people prefer to be associated with socially responsible banks (banks that are ethical, responsible and with fair prices). Lee et al. (2012) also argue that CSR is associated with trust which influences customer satisfaction and loyalty (retention). Social responsibility represents to some extent an abstract concept and therefore there is no uniform definition for CSR. Kotler and Lee (2005) state a definition of international organization Business for Social Responsibility which defines CSR as managing of business in such a way which surpasses ethical, legal, commercial and social expectations. Luo and Bhattacharya (2006) also define CSR as direct or indirect contributions to the society by performing socially responsible behaviors and/or engaging in actions that advance some social good or welfare. This is because businesses and communities are intertwined and therefore success depends on the good health of the society. Pérez and del Bosque (2012) also argue that the CSR concept appears to be one of the most effective tools a company can use to improve its public image. Banks are able to express their values and vision through CSR to their key stakeholders as well.

The above statement also implies that bank customers are the basic pillar of the existence of commercial banks because of their activities within the banking industry and therefore, their satisfaction from CSR actions is key for any commercial bank to exist. We investigate customers' satisfaction of banking services in Kenya and compare the results with those from Czech Republic. The results will be analyzed according to gender, age and level of education. Furthermore, the paper will provide the main reasons for customer satisfaction and dissatisfaction in commercial banks in Kenya compared to Czech Republic. The rest of the paper will be as follows. Section 2 discusses about CSR in commercial banks and elements that drive customer satisfaction. Section 3 outlines the development of scientific assumptions. Section 4 gives the results of the survey. Section 5 gives the results and finally section 6 will conclude this paper.

## **2 CSR AND CUSTOMER SATISFACTION IN COMMERCIAL BANKS**

### **2.1 CSR in commercial banks**

Socially responsible banking is becoming a well-established notion in the financial services industry (Scholtens, 2009). Many companies nowadays publish their CSR activities together with sustainable reports on their websites for their customers. CSR has many merits for these companies. These merits include increased profits, enhanced customer loyalty, enhanced brand attitude, trust and skirted negative publicity (Senthikumar et al., 2011). CSR is also used as a pre-emption strategy to save corporations from unforeseen risks and corporate scandals, possible environmental accidents, governmental rules and regulations and better relationship with employees based on volunteerism terms (Akanbi and Ofoegbu, 2012). Soana (2011) also states that CSR contributes to safeguarding corporate reputation by

lowering unpredictability in the event of harmful effects, such as the withdrawal of a product thus protecting profits and financial results.

These merits are achieved because of CSR integration of social, environmental, ethical, consumer concerns and human rights into business operations and core strategy in close collaboration with stakeholders (Ostalecka and Swacha-Lech, 2013). The authors further argue that implementing CSR into banks involves commitment to the economy, shareholders, customers, employees, society and environment. They explain the commitments as follows: economic commitment involves complying with both regulatory and supervisory legal norms. Commitment to shareholders involves achieving satisfactory rate of return, increasing effectiveness, risk management and improving of corporate governance to create shareholder value. Customers' commitment involves enhancing innovation, efficient customer service, creating good customer relationship and delivering of quality services and products.

For employees, it involves creating of opportunities basically for career development and also improving both work-life balance as well as corporate culture development. To the society, it includes undertaking projects within the society that are for instance related to education, innovation, and environmental consciousness. Environmental commitment is supporting and contributing to green economy development, for instance by coming up with environmentally friendly products and financing ecological projects. Implementation of these commitments contribute to sustainable development, creation of reputation and increasing profits.

Cheng et al. (2014) also argue that companies with better CSR performance and commitment achieve lower capital constraints. CSR leads to achieving of customer satisfaction, which makes it possible for customers to come back to businesses and give financial return to CSR (Luo and Bhattacharya, 2006). Consumers have taken the initiative to support such companies that engage in CSR (Green and Peloza, 2011). Loureiro et al. (2012) argue that the overall importance of CSR is consumer satisfaction. This is because CSR may not only contribute to better financial performance by directly reducing costs and increasing productivity but may also contribute indirectly by increasing customer satisfaction (Loureiro et al., 2012).

## **2.2 Elements that drive customer satisfaction in commercial banks**

Customer satisfaction is the primary criterion for the assessment of banks' relationships with the market (Munari et al., 2012). Banks with high level of customers' satisfaction are also able to be differentiated from their competitors thus making customer satisfaction an important aspect of retail banking (Walker et al., 2008). According to Halimi et al. (2011), as customers' satisfaction enhances, customers' loyalty also increases. This increase leads to high profits and market shares. Commercial banks have been forced to operate with emphasis on customer services due to strong competition and long-term achievement since it is linked to bank's ability to adapt in changes of customers' preferences and needs (Grigouridis et al., 2013). Chakrabarty (2006), mentions service quality as an accepted element of customer satisfaction as indicated by Parasuraman et al. (1994).

Banks are placing more focus on service quality in search of competitive advantage (Kumar et al., 2010). They further state that service quality is the primary competitive weapon used in differentiating bank products. Service providers are the primary source of service quality. Kumar et al. (2010) emphasize the need for banks to ensure service quality since it enables customer retention, customer loyalty and higher revenue. According to Berry et al. (2006), customers' assess services based on performances. These performances are based on the technical performance, tangibles associated with the service and the behavior and appearance of the service providers. All these performances play specific roles in creating the customer's

service experience, influencing both the rational and emotional perceptions of service quality (Berry et al., 2006).

Research by Wruuck (2013) for Deutsche Bank AG in Germany about pricing in retail banks, argues that bank prices play a significant role for customer satisfaction and profitability. The author further argues that customer satisfaction is achieved when price satisfaction actually matches customer's expectations. According to Matzler et al. (2006), customers switch banks because of price and therefore price is an important element of customer satisfaction. Situational and personal factors also drive customer satisfaction (Zeithaml and Bitner, 2000).

### **3 MATERIALS AND METHODS**

To compare satisfaction of bank customers in Kenya and Czech Republic, a questionnaire survey has been used as a method of data collection. Munari et al. (2013) argues that customer satisfaction surveys are the main source of information to set strategies aimed at meeting needs or understanding of customer perceptions, most importantly showing relationships and possible areas of improvement for customers. The questionnaires contained questions on gender, education, overall satisfaction, factors of satisfaction and factors of dissatisfaction. For Kenya, the survey was conducted in October 2014 to November 2014. Survey in Czech Republic was conducted in October 2012.

KPMG (2013) on their research on customer satisfaction on a sample of 25 000 banking customers across 14 countries in Africa, state that Kenya's bank customers are satisfied because of existence of branches of their respective banks. They also state that bank customers are dissatisfied because of high prices for services and products from banks. According to Belás, Burianová, Cipovová, & Červenka (2013), the most important factor of customer satisfaction in commercial banks in Czech Republic is the ability to use e-banking services while the most important factor of customer dissatisfaction is the high price policy of bank products and services. The above arguments have resulted to the following scientific assumptions for this research.

SA1: The overall levels of customers' satisfaction in banks in Kenya and Czech Republic are different.

SA2: The most important factor of satisfaction for bank customers in Kenya is the availability of branches, while the most important factor of satisfaction for bank customers in Czech Republic is the possibility to use e-banking. These levels of satisfaction are supported by more than 50% of the respondents.

SA3: The most important factor of dissatisfaction for bank customers in Kenya and Czech Republic are the same. These levels of dissatisfaction are supported by more than 50% of the respondents.

Descriptive statistics and also Pearson's chi-square test have been used to our analyze data. Our significance level is 5% (0.05).

### **4 RESULTS**

A total of 323 respondents completed the survey from the Czech Republic. Out of 323 respondents, 37% were women and 63% were men. A total of 403 respondents completed the survey from Kenya, of which 43% were men and 57% were women. Results indicate younger

age structure of Kenyan respondents, 81% were between 18 and 30 years old while 32% in the Czech Republic. This younger age structure has widely been used in this research because majority of the adult population above 30 years old use M-Pesa services (mobile banking for mostly unbanked) compared to the younger generation (18 to 29 years) who prefer using banks. According to KPMG (2014), M-Pesa functionality has more than 14 million customers (70% of Kenya's adult population). The age structure could have been considered as potential source of variances within results of the survey. However, our research was not focused on showing variances within the age structure rather focus on reasons for satisfaction or dissatisfaction within the age groups. Tables 1 and 2 below give the results of the overall level of customer satisfaction and reasons for satisfaction in Kenya and the Czech Republic respectively. The results are analyzed according to gender, age and level of education.

Are you satisfied with banking products and services provided?	In total	Gender		Age			Education level	
		Men	Women	Under 30 years	30 - 50 years	Over 50 years	University	Primary and secondary
Yes in %	63,80 (62,23)	58,70 (55,37)	67,50 (66,34)	64,40 (64,71)	63,90 (59,51)	20,00 (65,52)	63,70 (66,12)	64,10 (59,90)
No in %	32,80 (26,32)	39,00 (31,40)	28,10 (23,27)	31,90 (24,51)	33,30 (28,83)	80,00 (22,41)	32,70 (27,27)	35,90 (25,74)
Don't know in %	3,50 (11,46)	2,30 (13,22)	4,30 (10,40)	3,70 (10,78)	2,80 (11,66)	0,00 (12,07)	3,60 (6,61)	0,00 (14,36)
Critical values of $\chi^2$		5,990		9,488			5,990	
Calculated values of $\chi^2$		5,860 (3,894)		5,325 (1,315)			4,988 (4,499)	

**Note:** Data in brackets, ( ) refer to results for Czech Republic; secondary education has been used to also refer to respondents of primary education due to minimum number of responses.

As per the survey, 62% of Czech bank customers are satisfied with their respective banks, 26% are dissatisfied and 11% of them have no clue whether they are satisfied or not. Results have showed that 64% of Kenyan respondents are satisfied by their banks, 33% are dissatisfied and 4% did not know. Based on the above results of Czech and Kenyan bank customers, we conclude that the overall levels of satisfaction are different. Through this, our assumption No. 1 has been confirmed.

Tab. 2 - Reasons behind satisfaction of bank customers in Kenya and Czech Republic. Sources: Belás et al (2014), Belás, Burianová, Cipovová, & Červenka (2013), own source

What does satisfy you the most in your bank? (you can list up to three reasons)	In total	Gender $\chi^2=3,84000^*$		Age $\chi^2=5,99000^*$			Education level $\chi^2=3,84000^*$

	$\chi^2$		0,0001 (0,291)		3,302 (7,162)			2,199 (0,291)	

**Note:** Data in brackets, ( ) refer to results for Czech Republic; \* critical values of  $\chi^2$ .

According to the results, Czech bank customers are most satisfied with e-banking services (75%). This functionality is most important to women (79%) than men (68%). Another significant difference is that, e-banking is favored by people under 30 years old (89%) more than the other age groups i.e. 30-50 years (74%) and over 50 years (50%). It is also important to people with university education. Availability of the branches is the most important factor of satisfaction to people with primary and secondary education (56%) as well as people over 50 years old (53%) than people with university of education (38%) and the other age groups.

The most important reason for customer satisfaction in the Kenyan banking industry is the availability of branches. This is most important for the age groups of over 50 years old and under 30 years old. The test results also indicated that availability of the branch as the most important factor in all of our social groups. Statistically significant differences were found. Respondents with primary and secondary education preferred quick service at branches (44%) more than those with university education (26%).

For both the Czech Republic and Kenya results, significant differences are visible. The important reasons for customer satisfaction are different. This has confirmed our assumption No. 2.

While e-banking is the most important reason for satisfaction in Czech Republic, it is preferred more by people with university education and women. For availability of the branch as the most important reason for satisfaction in Kenya, it is preferred more by people with university education and men.

	$\chi^2$		1,504 (0,001)		2,612 (1,470)			3,803 (0,001)	

**Note:** Data in brackets, ( ) refer to results for Czech Republic;\* critical values of  $\chi^2$ .

High prices of products and services (65%) is the most important reason for dissatisfaction to Czechs. This factor is unanimously agreed upon in all of the social groups. Impersonal approach was chosen by men (21%) than women (9%). The second most important reason for dissatisfaction is slow services at branches followed by impersonal approach, poor acceptance of needs, poor accessibility of branches and poor quality of e-banking respectively.

The main reason for dissatisfaction of Kenyan bank customers is high prices of products and services (55%). This reason of dissatisfaction is the same as in the Czech Republic. This has confirmed our assumption No. 3. Moreover, Kenyan respondents perceive other factors of dissatisfaction such as slow services at branches (53%) and low acceptance of needs (42%) visibly more than Czech bank customers. The most visible difference is showed by poor quality of e-banking (34%) as the fourth reason for dissatisfaction in Kenya but the least reason of dissatisfaction in the Czech Republic (2%). For Kenya, e-banking is statistically important within the social terms of education level.

## 5 DISCUSSION

Our research has some similarities and differences with some of the previous works done about customer satisfaction in Kenya and Czech Republic. For instance, the overall level of satisfaction in Kenya is above 70% (KPMG, 2013). In comparison to our research, the overall level of satisfaction is 64% in Kenya. According to Belás et al (2014), the overall level of satisfaction in Czech Republic is 62%. For better information, the overall level of satisfaction

in Slovak Republic was 61% in 2012 (Belás, Holec, and Homolka, 2013). Based on our research results, the overall levels of satisfaction are slightly different between Kenya and Czech Republic.

It is further stated by KPMG (2013) that availability of branches (99%) is the most important reason for satisfaction in Africa. For our research, availability of branches (58%) is also the most important reason for satisfaction in Kenya. They further mention that developed network of ATMs (77%) as the second most important reason for satisfaction from a sample of 1 190 Kenyan respondents. Our research has developed network of ATMs (44%) as the third most important reason for satisfaction. According to a global survey carried out by Ernst & Young (2014) on customer satisfaction and behavior, e-banking (46%) is the most important reason for satisfaction for Czech bank customers and this is the same (75%) for our research. Global survey has showed that satisfaction with branch (27%) as a bank's channel is lower than e-banking and ATMs in the Czech Republic. Based on our research, the most important reasons for satisfaction are different.

High prices of products and services (70%) is the main reason for dissatisfaction in Africa's banking sector (KPMG, 2013). Based on our research, high prices of products and services (55%) is also the main reason for dissatisfaction in Kenya and in the Czech Republic (65%). Furthermore, low prices of products and services accompanied with service quality is considered as an important factor in creating customer loyalty for bank customers in Africa (KPMG, 2013). They further state that customers prefer to choose bank that are easily accessible and with cheaper fees and rates to indicate their satisfaction or dissatisfaction with commercial banks.

Authors Martinez and del Bosque (2013) argue that CSR has an immense effect on customer satisfaction. Furthermore, Belás, Cipovová, and Demjan (2014) mention that a satisfied customer is of great importance for the current and future performance of commercial banks.

These findings are important for commercial banks that are focused in using CSR to improve customer satisfaction. This is because customer satisfaction as a result of CSR activities leads to customer loyalty, profitability and increased market share in the banking industry as mentioned in our research. The results are also important for commercial banks and researchers who want to compare levels of satisfaction and dissatisfaction between Kenya (Africa in general) and Czech Republic (other EU countries).

## **6 CONCLUSION**

The purpose of this research was to look at customer satisfaction as an influence of CSR activities in commercial banks. The countries for research were Kenya and Czech Republic from samples of 403 and 323 people respectively. CSR leads to customer satisfaction through retaining customers thereby increasing profits and high market shares for companies. Elements such as service quality, pricing, situational and personal factors drive customer satisfaction. According to the literature used, for banks to implement CSR activities, they must be committed to the economy, shareholders, customers, employees, society and the environment (Ostalecka and Swacha-Lech, 2013).

Based on the findings, the overall levels of satisfaction in Kenya is 64% and 62% in Czech Republic. This has confirmed our assumption No. 1 that the overall levels of customers' satisfaction between the two countries are different. Women are satisfied more than men between the two countries.

The most important reason for satisfaction in Kenya is the availability of branches (58%) while in Czech Republic is e-banking functionality (75%). According to our research, the results have confirmed our assumption No. 2. Both the reasons are preferred by people with university education. However, women prefer e-banking more than men in Czech Republic and men prefer the availability of branches more in Kenya. High prices of products and services was chosen as the most important reason for dissatisfaction for Kenyan and Czech bank customers. They both were selected by 55% and 65% of the respondents respectively. These results confirmed our assumption No. 3.

Future research should focus on the possible ways commercial banks in Kenya can improve customer satisfaction through the use of e-banking. This recommendation has been arrived at because of the popularity of e-banking in the 21<sup>st</sup> century and the response from our survey. It also gives an opportunity for commercial banks to tap into the younger adults (18 to 29) and to make use of many internet subscribers in Kenya. According to KPMG (2014), there are 14 million internet users in Kenya. As a managerial recommendation, commercial banks should come up with policies or measures to tackle reasons for dissatisfaction, most importantly high prices of products and services.

## **ASPECTS OF CREATING SHARED VALUE IN BATA UP TO 1945 – APPLICATION MODEL FOR TODAY**

*Gabriela Končítková*

### **Abstract**

The concept of CSV (Creating Shared Value) is currently perceived as a modern trend, as an output or higher level of CSR (Corporate Social Responsibility). The simplest definition, which highlights the difference between CSR and CSV, states that the goal of CSR is to do good whereas the goal of CSV is to do good business. But conceptions may vary. The main objective of this paper is to prove that the issue of CSV is not a modern trend, as it is often called and perceived. This business concept was used and enhanced by Tomas Bata (1876-1932) when building his shoe empire. The business philosophy of Tomas Bata covered all the factors by which we nowadays evaluate whether a company is progressing in line with CSV or not. Bata established businesses closely connected with the local communities, not only in Zlin but throughout the world. Individual company branches were fully dependent on communities, which created a significant percentage of the company's staff. Bata did not merely consist of a large number of branches worldwide, but it also affected the social development in all areas of social life in the places where it had operations. It was a clear application of the CSV policy.

Aim of the research is to prove that the Bata Company developed its business activities according to values of the same CSV strategy as used today.

This article presents the partial results of research that focuses on answering the following question: Why nowadays days are not only Czech, but also international companies, seeking inspiration from the Bata Management System?

## **1 CREATING SHARED VALUE AND CORPORATE SOCIAL**

Each theory and approach can seek shared value in varying fields and areas. Some authors talk about shared values from a global perspective, impact the whole of society, other authors argue for the need to create value for the company's immediate community. Importance of shared values can be seen in production activities, employee care, development of public facilities and responsible investing. Porter and Kramer (2014) define the concept of CSV as attitudes and practices that enhance the competitiveness of companies, simultaneously with the economic and social conditions in all areas in which it operates. CSV focuses on identification and expansion of the links between social and economic development. The authors agree that the CSV has the power to unleash the next wave of global growth. Porter and Kramer (Junge, 2011) emphasize that current interdependence that exists between corporations and their surroundings means that both sides should pursue the principle of creating shared value for mutual benefit. In other words, they point out that successful corporation requires a healthy social environment whilst a healthy social environment requires a successful corporation.

The authors state that better educated children will become more skilled workers and that a low unemployment rate in cities will result in a higher consumption level amongst the population. Therefore, companies should integrate the principle of shared value into their business approaches and strategies, and use it to their competitive advantage. An increase in shared value can also be seen also in sport. This theme is described by Woong, Hyun-Woo and Yukyoum (2015) who highlighted the importance of human perception of such areas as history and identification. The overall concept of CSV is based on the nature of identification. To create CSV, the first important step is to identify the creator and the object.

If we focus on finance, for example, Belas (2013) points out in his study the need for banks to behave responsibly towards their clients, but also towards the community in which they operate. These conclusions are based on extensive research into customer satisfaction with banking services. This research clearly shows that nowadays a client expects and requires the bank to produce "extra activity" that would support community development (Belas 2013).

Bata up to 1945 is a rare example of a company that became a leader thanks to gradual increase of shared value within individual areas. Ghasemi, Nazemi and Hajirahimian (2014) state that CSV can be described as a development stage of CSR. The authors also defined the basic requirements that a company needs to fulfil in order to be able to transform from CSR to CSV.

To understand CSV we need to understand the tools used to measure or assess examples of it. This area requires substantial innovation (Pfitzer, Bockstette and Stamp, 2013). The authors propose the creation of an optimal structure for CSV innovative models. These models are undoubtedly closely related to the economic consequences of CSV. Critics of CSR and CSV models point out that many companies are unable to pay workers an average wage, but they would like to develop CSR and CSV strategy. Wage ratios motivated Tomas Bata to create a CSV strategy that would guarantee above-average wages for employees. Bilan (2013 and 2014) draws attention to the issue of wages in relation to shared responsibility. One can say that the study was conducted with Tomas Bata's words in mind: "The level of development of a nation is recognized by the wages of the population" (Bata, 1932). Therefore it is not possible to plan a CSV strategy regardless of economic conditions inside the company. CSV strategy should primarily focus on employees and subsequently on the community and society. CSV and CSR strategies should not be just a fashionable trend, but an approach to make the business activity improve community life around the company and in the wider context also on a global scale. De Jonge (2014) points out the direct impact of CSR and CSV strategies on public. He applied his study at WestJet Airlines and demonstrated direct influence of CSR and CSV strategies.

This approach becomes very important when companies decide to expand their market scope towards emerging economies and markets with generally low income. In these cases, there must be a link between the company and socially strongest companies. According to the theory of Porter and Kramer, the concept of shared values should reduce the risk within their value chain to the receiving companies.

Company should also apply a philanthropic strategy which would have a positive impact on competitive advantage. Finally, it is necessary to create an approach where social sector is perceived as a common value. Modern multinational companies transform their own CSR approach in order to create the CSE, or socially responsible business.

## **2 THE LEGACY OF CREATING SHARED VALUE IN THE CZECH REPUBLIC IN THE EARLY 20TH CENTURY**

Bata was established in 1894 and on the way to achieving sustainable growth experienced 30 years of conducting business and overcoming obstacles. For Bata steady growth is only noticeable from 1924 onwards. From a small family enterprise, which started business in shoemaking - a challenging and competitive sector, it grew into a company which in 1928 turned out to be the largest exporter of footwear in the world.

Bata used CSV strategy not only in Zlín, but also in other cities where its branches were founded. In addition to its core business activities, the company cared also about other areas of social life - infrastructure, housing, public facilities, education system, health and social care.

How did Tomas Bata manage to create a perfect information system within his company? Thanks to his unique system every week he was found out the exact operational results of every branch in the world, all without use of IT. Furthermore, how is it possible that people worked for Bata with enthusiasm and were rewarded with salaries three times higher than the national average? Entrepreneurs nowadays these questions and many others, and search for the answers in the Bata Management System. The Bata Management System is a term for the business practices, strategy and overall philosophy of Bata, developed between 1894-1945 by Tomas Bata and his associates and followers.

Currently, it is still possible to observe the direct effects of the business philosophy of Tomas Bata on particular people. Through oral history it is still possible to record the personal stories of people who worked at Bata and completed their education and training there. These people stand as a proof of the active and successful operation of the company's philosophy and strategy. The Original Bata Management System can only be defined up until 1945 when the company was nationalized. More than 70 years have passed since the last displays of pure "Bataism", but witnesses who lived through this time remember it very vividly. Managers and entrepreneurs nowadays often wonder how Bata managed to change the way of thinking of the local people (employees, customers, residents etc.). Many companies are dealing with the same problem - human resources. High-quality and loyal employees have become scarce. Many companies are addressing the same question: If you cannot find quality employees on the labour market, can you train them? Tomas Bata was able to gain his employees' trust, loyalty and in particular managed to merge corporate culture, vision and philosophy. This concept corresponds to Bata's theory of an industrial man as described later in this text.

Due to the breadth of the concept of the Bata Management System, it was important to choose just one area for this research project - an area in which displays of CSV could be mapped and applied to the current business environment.

In light of the aforementioned problems of modern business environment, the research focused on the personnel policy of Bata up to 1945 and the CSV tools used for its realization. Individual areas were defined within the research, in which Bata applied CSV principles in the field of human resources and employees' care. There were good working conditions, a good education system, social system, health care system, housing facilities and cultural and sports activities for employees. The individual areas of Bata's CSV policy towards employees are described in detail below.

### **3 RESEARCH METHODOLOGY**

Aim of the research is to prove that the Bata Company developed its business activities according to values of the same CSV strategy as used today. Therefore CSV strategy cannot be perceived as a modern tool. The second objective of the research is to prove that the Bata Company applied CSV first to employees. After achieving the first two objectives, the third goal is to create an application model that would help companies build a business by the same strategy as Tomas Bata did. The main objective of this paper is to present parts of the development strategy of the Bata Company up to 1945 which can be perceived according to current indicators as CSV manifestation. Partial aim of the research is to determine whether the current companies are interested to apply CSV strategy elements of the Bata Company into their businesses.

The first part of the research is dedicated to the research of archival documents and interviews with witnesses who lived through this exceptional system. This part of the research is based mainly on the use of qualitative research methods.

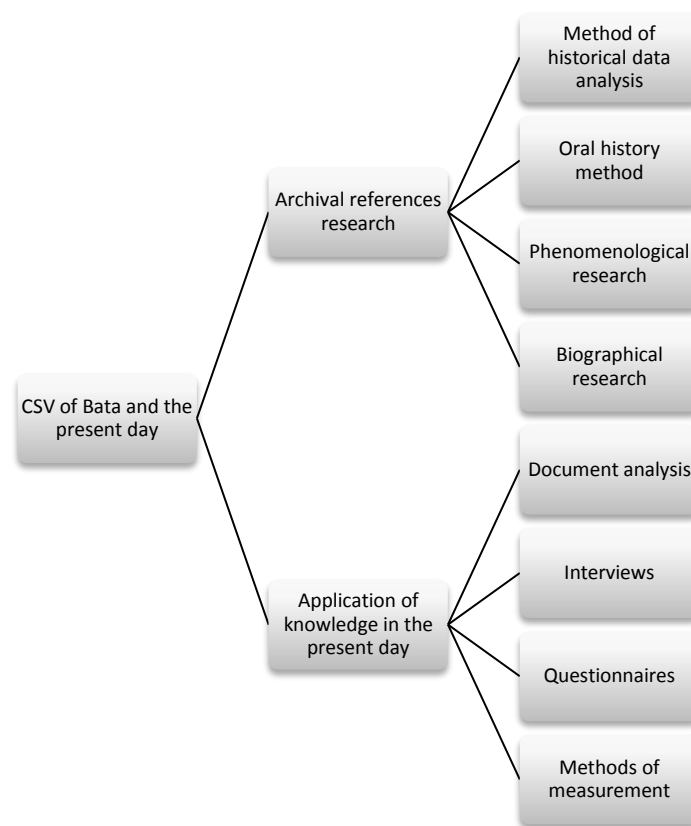

Fig. 1 – Scheme of research methodology. Source: author.

#### **3.1 Methodology of archival references**

The research methodology of the historical questions on Creating Shared Value in the Bata control system is associated mainly with a comprehensive analysis of historical documents that are stored in archives. Currently it is possible to study the daily activities of Bata through historical documents that are stored in national archives with a special section for Bata company archives. The methodology for processing the papers is divided according to

research methods that are related to the processing of archival documents and personal testimonies of witnesses. These methods are:

Historical data content analysis method - through this method it is possible to examine archival documents that are stored in the Moravian-provincial Archives in Brno, with a satellite office in Zlín. The archives store documents on the operation of Bata up to 1945 - circulars, daily reports, regulations, guidelines, reports, newspapers, etc.

Phenomenological research method - includes all documents and archival documents related to the social approach which was and is considered to be a phenomenon. This research method can only be connected to the facts that show characteristics of the phenomenon. Within the framework of the phenomenological research documents such as newspaper articles, contemporary media reports, historical studies and other information can be processed.

Oral history method - thanks to this method it is possible to gain valuable insight into the functioning of Bata up to 1945 based on the personal experiences of witnesses who were directly involved in the Bata Management System.

Biographical research method - this method focuses on the research of biographical materials. This type of material includes personal photographs of witnesses, personal notes and things of witnesses who were direct participants of the Bata Management System up to 1945. These materials can be found in private collections of the witnesses.

The research methods cannot be separated from each other as many of them are interlinked. The topic of research of two different methods can be the same; each of these methods, however, looks at the topic from a different angle.

The close connection can be seen especially between the oral method of research and biographical research. Both methods are based on the personal relationship of the witness to the time period. However, one focusses on interviews with witnesses, whereas their personal belongings related to the research issue are only additional and illustrate the situation - as is the case of the oral history. The biographical research method is the exact opposite: the main subject of the research is the personal belongings of the witnesses and their experience only illustrates the research.

The biographical research method is also closely linked to the research method of historical data analysis. Both of these methods examine and analyses historical documents related to the topic of research. The phenomenological research method appears across all research methods and deals with the problem from the phenomenon perspective, i.e. it examines if the topic of research can be considered as phenomenon or not.

Research of historical data is different from conventional research which is linked to the economic sciences. In contrast to other studies, historical research can be initiated only by setting goals and not by asking research questions. With historical research it is common that a researcher merely needs to determine the reality of a phenomenon without having to examine the problem by asking specific questions. Before beginning the research, the researcher often does not know what direction the research question should aim.

#### **4 BATA AS AN EXAMPLE FOR CSV BUSINESS STRATEGY**

As already mentioned, Bata did not enter the market with a unique product that would guarantee a leading position on the market. The company started business in an industry that was known for being a challenging competitive environment. Bata operated in two main areas. The first area was producing footwear which was happened from the very beginning.

The second area was the production of tires which dated from 1931. The company managed to create a stand-alone corporation for these two main production activities, which gradually became independent of suppliers and drew on its own activities, covering the needs of the company. In addition to these activities, Bata managed to develop hospital care, a school system, infrastructure, housing, social welfare, cultural and sports facilities, as well as transportation and other activities that will be presented in detail below.

Prior to its expansive growth Bata had to overcome the fundamental problems faced by most companies during their operations. To stabilize the company on the market, it was necessary to:

1. Secure stable suppliers.
2. Secure smooth and efficient production.
3. Secure sales.

Tomas Bata used to say that "he did not build a factory but a man who built a factory." The fundamental prerequisite for the rise of Bata was an educated employee who would be able to live in a modern metropolis. Under the influence of Bata, the town of Zlín developed into a modern city called "a garden city". Before Bata launched its business in Zlín, it was only a small village of three thousand inhabitants. During the thirty years of Bata in Zlín the population increased by more than twelve times. The municipality itself was not able to fully reflect the rapid pace of the company growth.

Tomas Bata wanted to provide to his co-workers (in Bata they did not use the term employee, but rather co-worker for the simple reason that they all had a common goal and they had to work together to achieve this goal) with services and facilities through Bata's activities. This was necessary because neither the town of Zlín nor other businesses were able to keep up with the growth of Bata. Thus Bata, through its operations and activities, also started to support the growth of surrounding businesses, the town and public institutions.

As mentioned previously, there were two key motifs of Bata which had led to the increase of shared values and could not be separated. Bata was a leader in production trends and aimed to be the best on the market. But this goal could not be achieved without a well-trained staff. The company would not be able to provide facilities for the training and education needed for its employees if they relied solely on the existing town facilities and public institutions. The company had to be very active in this area.

The education of the so-called "industrial man" (this term will be defined later), however, had a significant impact on education in Zlín and its surroundings. It also led to a societal change and increase in social values.

This relationship is illustrated by the following picture:

Fig. 2 - Model CSV. Source: authors.

1. The Business - Bata identified the needs of educated and skilled employees. For this purpose a new term was created - "industrial man." The "Industrial man" was a person, who:
  - worked in the factory,
  - had an above-standard income,
  - developed and enhanced his work activities,
  - was active in life-long learning,
  - lived in his own Bata house,
  - had a good family and social background,
  - had a healthy lifestyle,
  - had good quality health care,
  - engaged in cultural and social activities,
  - achieved a balance between work, personal development, family and social life.
2. Every employee (co-worker) of Bata Company was to become an "industrial man". Moving from point 1 to point 2 was possible only through action, thanks to which social values also increased. It was possible to achieve this objective only through the Bata's own initiative.
3. However, CSV activities of Bata were not aimed only at employees of the company, but they were also available for the residents of Zlin and its surroundings. Through these activities Bata fundamentally influenced the standard of living in Zlin.
4. The resulting increase in living standards led to changes to the population of Zlin. The company's activities began to impact all residents and social life began to evolve. Several of the company's activities could avoid involvement of residents even if they wished for that.

In the current economic climate this situation is called "the inability to exclude the subject of consumption". For example, the company carried out construction of roads, sidewalks, street lighting, planting of greenery in the town centre etc. Details of these activities will be provided in the following diagram.

It is clear that, due to the activities of Bata, social values evolved and thus life in Zlin was influenced greatly. Bata has not applied this model only in Zlin, but also in other cities around the world where its affiliates were based. Therefore it is not possible to say that this was just an isolated phenomenon which has been linked to the city of Zlin and the former Czechoslovakia.

#### **4.1 CSV of Bata in various fields of interest**

In this part of the article I would like to introduce all levels of CSV strategy in Bata. To some extent this strategy resembles Maslow's hierarchy of needs. However, the pyramid displayed below corresponds to the timeframe of the development of activities in Bata. Tomas Bata himself made several trips to America where he became fascinated and inspired by flow production, and also by the life of the industrial man. He understood this philosophy very quickly and put it into practice in Zlin. He realized that he could build a great company only

with great people who would share his vision and would not be distracted by worrying about their housing, food, health care or education for themselves and their children.

Tomas Bata needed his colleagues to concentrate on the development of the company without any distraction which is why the company provided for and fulfilled all the other needs of its employees. First the company covered the food, housing and job security needs (this evolved and developed in line with the times). Consequently, it was necessary to provide social facilities for employees and their families so that the employee was aware that the company cared about their personal life. At the same time professional health care began to develop. In the field of health care the company achieved significant results based on prevention and education. Social life played another very important role in the company. Tomas Bata believed that one should work eight hours a day, eight hours should be spent on personal development, family and culture, and eight hours for sleep.

Cultural, social and sporting life in Zlín was very diverse. Education and personal development played an essential part in shaping the "industrial man". Only a man with desire to learn and grow was fit for Bata. All these activities meant that co-workers of Bata fully shared the corporate philosophy and vision as corporate activities interfered with their lives at every stage and in every area of life. These stimuli led to the creation of the so-called "industrial man" as shown below:

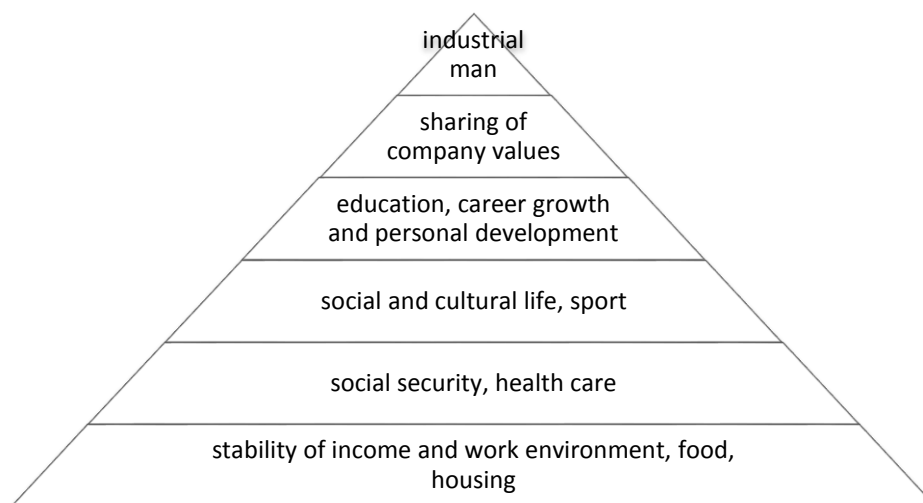

Fig. 3 – Pyramid of the industrial man's needs. Source: authors.

All areas in which the company operated influenced public life in the town and the overall development of the town.

In the public sector, this meant primarily financial support for the public administration and creating initiatives during the process of decentralization of the administrative authorities to Zlín. An initiative to supply housing for employees was introduced as part of Bata's urban development. Thanks to this initiative entire neighbourhoods were created for the employees. The rent for these houses was very low, but the house rules were very strict. The company also built a power station, sewage disposal, roads, sidewalks, sewage system, street lighting, etc.

As part of public facilities, Bata guaranteed the development of services and availability of goods in Zlín. The company started its own shops, trying to deliver good quality food so that their employees could eat healthily. The company also set up catering facilities - canteens and cafeterias, where it was possible to find high quality food for better prices. The company took

a phenomenal approach to creating its own educational system, which was able to fully replace the state education system.

The company established several nursery schools and specialized primary schools which were based on a Waldorf model, and a full range of secondary schools, from famous Bata schools to industrial schools in various fields. Special attention was also paid to lifelong learning - school for newly recruited employees, Sales school, Flying school or Export school. Tomášov, the institution for future senior level managers was another special educational institution. In the field of education Bata also placed great emphasis on the teaching of foreign languages.

Significant results were achieved in the field of social and health care. Bata needed healthy staff, and so it began to develop a whole range of activities aimed mainly at preventative health, safety regulations in the company, access to health care, mandatory health checks and more. These activities resulted in the establishment of Bata's own hospital and plans to build a so-called "House of Health", but this project was interrupted by the Second World War. This activity, the primary aim of which was to improve the health of employees, had an impact on the overall improvement of the health of the residents of Zlin and its surroundings.

Cultural and sporting life was also very important. The company founded many sports and cultural institutions. These institutions included a cinema, hotel, swimming pool, sports facilities and more and were also widely used by citizens who were not employed by Bata.

The close connection between the areas is shown in the figure below.

Fig. 4: Connection between the areas of Bata's CSV. Source: author.

## **5 COMPANIES NOWADAYS AND THE CSV HERITAGE OF BATA**

The current attitude of companies towards the utilization of Bata's CSV heritage has been analysed in companies which began following the Bata model on their own initiative. The research is carried out based on a combination of quantitative and qualitative methods, which are described in Methodology chapter. The research was carried out in seven companies. These firms are from industries and of different sizes. A common characteristic of these firms

is that the owner or top manager seeks inspiration from Bata Management System. These managers and owners were interviewed in order to find out the motives which have led them to seek the inspiration from the Bata Management System. Although their answers varied, it was possible to find certain common points. For example: “In the Bata Management System we have started to see a concentration of current theories about motivating people and their leadership, the integration of processes into company culture and many others. It is necessary to point out that the information was in a comprehensive and understandable form.” At the same time, the analysed parties agreed that the Bata Management System was based on the needs of Czech people and has aspects that are tailored to the mentality of the Czechs.

Choosing a company suitable for inclusion in the research depended on the company’s interest in increasing the involvement of employees in corporate culture. A common feature of the companies was the need to improve their personal activities and self-defined situations that the company has been facing, especially the problems in processes that depend on human activity.

There were a number of possible answers on a sliding scale to the question of why a firm would want to become a company which increases social value through its activities. The highest percentage of compliance is seen in this answer: “The need to create a better environment for future generations” and “The need to deal with personnel issues”.

However, when analysing these activities, it transpired that they are more focused on increasing social value amongst disinterested people rather than their own employees or stakeholders. At the same time, each of the interested companies displayed a need to increase the efficiency of internal human processes. So the question remains: why not increase social value for one’s own employees first, then for the community and then for the whole of society, as Bata did up to 1945.

This situation is illustrated by the following figure:

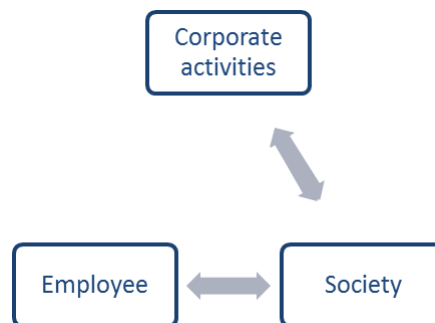

Fig. 5: Model of malfunction of CSV activities of firms. Source: author.

Setting a specifically definable goal is the main condition for the establishment of a strategy for the successful application of principles which will lead to the development of CSV based on the Bata Management System. Companies themselves should define what their goal is. Managers in many cases could not decide whether their goal is increasing the real value or mere profit maximization, although neither is mutually exclusive.

The application model for introducing the CSV inspired by Bata’s philosophy is based on man. Man is seen from all perspectives of human life and development, and should reflect the needs, wishes and dreams. Knowledge of these gifts lets you create a high quality motivational strategy for the company that leads to an understanding of proper CSV activities.

After analysing and processing personnel actions, each employer must know the motives of his employees in the various areas of their lives:

- Everyday activities at work
- Long-term activity at work
- Personal motives and interests
- Family motives
- Social motives

Based on the knowledge of these themes, a matrix of motives and needs of a company has been created. In places where the individual matrix points meet each other, there is space for a company to influence its employees. In these areas, the company should begin to develop activities that will exceed the obligations and rights of the employer and the employee will develop increasing interest for shared values in the area. It is necessary to transfer this model beyond the corporate culture. Beyond the confines of corporate culture, it is necessary to interest the community in which the company operates in its operations. Only then it is possible to find new ways to increase shared values.

The matrix of motivations and needs is the part of the application model which produces the results of the research.

## **6 DISCUSSION**

There are two main conclusions to be drawn from the above discussion. The first conclusion is a finding that the behaviour of the Bata Company up to 1945 exhibits elements of CSV strategy. On the basis of this finding, the CSV strategy cannot be perceived as something modern. CSV strategy may still be considered a more specific and higher conception of CSR strategy. We might as well continue to talk about the fact that CSV strategy can be applied by current companies and therefore it is a current trend. However, it is not modern or new trend, since the strategy was used to develop the Bata Company between 1894 -1945, not only in the Czech Republic but also abroad.

Potter and Kramer refer in their studies to the fact that CSV is a trend which present times call for, because business environment cannot be sustainable without a change in the concept. It is not necessary to refute this statement, but we also cannot claim that the current business environment is in the same situation as the Bata Company was. Upon further research some day we may be able to say that the Bata's CSV model is the best for sustainable business growth, not only in domestic environment but also abroad.

Personal interviews and surveys in companies, that follow the legacy of Tomas Bata, demonstrate that domestic companies understand better the CSV model in the context of the Bata Company than in the context of modern foreign companies. Based on data obtained in these companies it will be possible to use quantitative research methodology and principles of CSV application inspired by the Bata Company up to 1945.

## **7 CONCLUSION**

The presented article informs research on creating application model for developing CSV strategy in modern-day companies that are inspired by the Bata Management System legacy. These companies serve as an example for others looking for solutions on how to streamline

work in the field of human resources whilst creating shared value for the local community and stakeholders.

Aim of the research is to prove that the Bata Company developed its business activities according to values of the same CSV strategy as used today. These activities are converted into a model. Subsequently, this model will be adapted to the needs of the current business environment and legal framework. Based on the comparison of these models, an “ideal model” is established. Following that a distance test is developed. The distance test is the name for the method by which each firm can assess how far it is from the “ideal model” and work out what steps it must take in which areas and at what level in order to get closer to the ideal state. Consequently, methodological documentation on the individual steps and method for implementing Bata’s CSV in the current business environment has been developed.

To verify the functionality of the model and its impact not only on internal employees, but also especially on community life, it will be necessary to monitor the progress of the implementation and its impact over the coming years. This is not a short-term process and results could not be measured and evaluated immediately. The model in Bata developed over almost 30 years. Only after that was it possible observe its direct consequences on society on a global scale.

The basic principal for the application of a CSV model is to focus on employees as people who perceive the everyday needs of human society. Even today, in some companies one can find certain models that perceive humans only as an executor of tasks without any behavioural aspect to his personality.

In the application model, the object of development is an employee who should, through CSV, develop the community and encourage the development of shared values through the company and environment.

## **RECENT TRENDS, CHARACTERISTICS AND PROSPECTS OF PAYMENT CARDS IN THE SLOVAK REPUBLIC FROM THE PERSPECTIVE OF CLIENTS**

*Korauš Anton, Kiseľáková Dana, Demjan Valér, Cibák Ľuboš*

### **Abstract**

Payment cards continue to replace cash and checks in advanced economies. Along with the growth of payment card transactions has come greater scrutiny by public authorities of certain payment network rules along with the level of certain fees. This article reviews recent trends, characteristics and prospects of payments cards in the Slovak Republic from the perspective of clients.

The aim of this article was to examine recent trends, characteristics and prospects of payments cards in the Slovak Republic from the perspective of clients. In accordance with this objective, satisfaction as well as factors of this satisfaction and dissatisfaction, behaviour and decision-making of clients in Slovakia have been analyzed in relation to a gender, age structure, and level of education of customers.

The results of this research confirmed the overall level and factors of satisfaction, behaviour, and decision-making of banking clients. However, there are also significant differences in the opinions, ideas and decision making process and factors of satisfaction and dissatisfaction of bank clients in Slovakia within individual social groups. New payment technologies enhance consumer satisfaction and generate substantial efficiencies.

*KEYWORDS: payment cards, credit cards, debit cards, commercial banks, satisfaction of bank clients, reason for satisfaction of clients, behaviour of banking clients, decision-making of banking clients*

JEL Classification: G21, M14, M12, M31, Z13

## **1 INTRODUCTION**

Belás et al. (2013a) argues that the commercial bank as other business subjects achieves its basic goals through purchasing banking products and services to its clients. Customers in business relationships require a high level of acceptance of their needs from staff and accurately provided services (Lages & Piercy, 2012).

Payment cards continue to replace cash and checks in advanced economies. Along with the growth of payment card transactions has come greater scrutiny by public authorities of certain payment network rules along with the level of certain fees. This article reviews recent trends, characteristics and prospects of payment cards in the Slovak Republic from the perspective of clients.

At the end of 2013, Slovakia had issued 4.79 million payment cards, representing an increase by 4.4%. Highest annual increase (+ 78%) was observed in the case of contactless cards, which is now currently 2.15 million units (45% of all cards). Any thirteenth payment card in 2013 was carried out contactless.

## **2 THEORETICAL BACKGROUND**

The proliferation of payment cards has dramatically changed the ways we shop and merchants sell goods and services. Today, payment cards are indispensable in most advanced economies. Amromin and Chakravorti (2009) find that greater usage of debit cards has resulted in lower demand for small-denomination bank notes and coins that are used to make change in 13 advanced economies. Recent payment surveys also indicate that consumers are using payment cards instead of checks. Juřík (2012) states that aside from making money transaction more comfortable, the cards have been also used to increase loyalty of customers. This is why they are sometimes referred to as loyalty payment cards or personal payment cards.

Wider acceptance and usage of payment cards suggest that a growing number of consumers and merchants prefer payment cards to cash and checks. In addition, payment cards may allow access to credit that can be used to attract consumers without funds. Debit, credit, and prepaid cards are three forms of payment cards. Debit cards allow consumers to access funds at their banks (defined broadly as depository institutions) to pay merchants; these are sometimes referred to as “pay now ” cards because funds are generally debited from the cardholder’s account within a day or two of a purchase. Credit cards allow consumers to access lines of credit at their banks when making payments and can be thought of as “paylater ” cards because consumers pay the balance at a future date. Prepaid cards can be referred to as “pay before” cards because they allow users to pay merchants with funds transferred in advance to a prepaid account. Greater usage of cards has increased the value of payment network operators.

Our analysis also draws upon a model by Bolt and Chakravorti (2008a). They study the ability of banks and merchants to influence the consumer’s payment instrument choice when they have access to three payment forms-cash, debit card, and credit card. Their analysis combines elements of “two-sided” models that stress price structure with those that consider consumers’ liquidity constraints and security concerns. In addition, they consider how banks set prices when they participate in multiple payment networks (“payment substitution”). Much of the payment literature focuses on the intensive margin-how fees influence usage-instead of the extensive margin-how fees affect adoption-or does not distinguish the two. Notable exceptions are Bedre and Calvano (2009), Bolt and Chakravorti (2008a), and Chakravorti and Roson (2006).

Examine the level of satisfaction, decision making and behaviour of bank customers to the banking business is very important not only from a practical as well as theoretical aspects.

Belás (2014) points out that several authors examine the issue of satisfaction of banks’ clients in the context of bank management. Munari et al. (2013) indicate that customer satisfaction is becoming a stable goal of banking marketing policies, an important element for strengthening corporate reputation. Chavan, Ahmad (2013) state that the bank business increasingly depends on the quality of the customer service provided and overall satisfaction of each single customer. Relationship marketing has become the most critical aspect of corporate banking success. According to Grigoroudis et al. (2013, p.21) “the long-term success of banking organizations is related to their ability to adapt to changing customer preferences and needs. For this reason customer orientation and a continuous improvement in philosophy is adopted in order to design and provide products and services that meet customer requirements. This justifies the importance of internal and external service quality assessment and incorporation of quality measures in the performance evaluation of business organizations. Belás at al. (2014) argues that furthermore, the ability of banking institutions to respond to changing market conditions may provide a significant competitive advantage against competition”.

Clients generally demand quality from their banks as well as want them to understand their needs in order to be able to respond appropriately. Lages and Piercy (2012) suggest that clients in business relationships require a high level of acceptance of their own needs from staff and accurate services.

### **3 MATERIALS AND METHODS**

Given the purpose and objective of the research as well as the intended target group described in the research assignment, it has been decided to conduct an Usage & Attitude survey focusing on clients of Slovak banks. For this research in the year 2014 were used the methodology CAWI (Computer Aided Web Interviewing) on National On-line panel which contains more than 30.000 members in the Slovak Republic. This allowed us to cover required sample while respecting representative distribution of basic socio-demo easily.

#### Basic inputs for research

*SAMPLE SIZE: N=700 interviews in Slovakia*

*TARGET GROUP: Respondents aged 18 – 69 y.o.,*

*LENGHT OF THE QUESTIONNAIRE: 20 minutes*

*FIELDWORK: 2.6. – 26.6. 2014*

representatively distributed into gender, age groups, education level, region and city/village size.

Chakravorti at al. (2014) argues, that the Internet has come of age. Twenty-one years since the marketplace first took notice, the World Wide Web today is at the heart of the global economy, channelling interactions for nearly 40% of the world's population. Computer-assisted web interviewing is a Internet surveying technique in which the interviewer follows a script provided in a website. The questionnaires are made in a program for creating web interviews. The program allows for the questionnaire to contain pictures, audio and video clips, links to different web pages, etc. The website is able to customize the flow of the questionnaire based on the answers provided, as well as information already known about the participant. It's considered to be a cheaper way of surveying since you don't need to use people to hold surveys unlike Computer-assisted telephone interviewing.

Chakravorti and To (2007) consider a scenario with monopolist merchants and a monopolist bank that serves both consumers and merchants where the merchants absorb all credit and payment costs.

Chang and Krosnick (2010) argue that surveys showed that data collected via the Internet manifested higher concurrent and predictive validity and less random and systematic measurement error than data collected via telephone interviewing. With the increasing use of the Internet, online questionnaires have become a popular way of collecting information. The design of an online questionnaire often has an effect on the quality of data gathered. There are many factors in designing an online questionnaire; guidelines, available question formats, administration, quality and ethic issues should be reviewed. Online questionnaires should be seen as a sub-set of a wider-range of online research methods.

Krosnick (1999) about technological innovations in questionnaire administration expresses its view that these innovations have clear advantages for improving the quality and efficiency of questionnaire administration. Krosnick and Presser argue (2010) that researchers who compose questionnaires should find useful guidance in the specific recommendations for the wording and organization of survey questionnaires.

During research proceedings, two hypotheses and three scientific assumption have been established where methods of expert estimate during quantitative criteria establishment have been used.

*SA1: The overall satisfaction level of clients with payment cards is higher than 70 % in our research.*

*SA2: The most significant factor in client's decision on using the credit cards are the fees, while the impact measure of this factor will be over 50 %.*

*SA3: The most significant factor in client's decision on using debit cards are the fees and card issuer, while the impact measure of this factor will be over 50 %.*

*H1: The customers' satisfaction is not significantly determined by their gender, and achieved education structure.*

*H2: The customers' satisfaction is significantly determined by their age.*

## 4 RESULTS

Scientific assumptions have been verified through descriptive statistics indicators. The percentage calculations and weighted averages have been used.

In the survey, 646 respondents have been approached where 43.96 % of them were males and 56.04 % were females. The age structure of respondents is as follows: 40.86 % of them are aged under 30 years, 59.14% are over 30 years. The education structure of respondents is as follows: 1.12 % of them have achieved primary education, 63.75 % are secondary education graduates and 35.13 % are university graduates.

Established scientific assumptions in each table were examined through Pearson statistics. P-value less than 5% leads to rejection of the null hypothesis.

Tab. 1 - Overall customer satisfaction with banking payments cards and services

Are you satisfied with banking payments cards and services provided?	In total	Gender		p-value	Age		p-value	Education level		p-value
		Women	Men		Under 30 years, old	Over 30 years old		Primary and secondary	University	
Yes	523	293	230	0.98404	214	309	0.96012	340	183	0.87288
No	78	44	34	0.9442	32	46	0.97606	50	28	0.88076

Source: created by authors.

The level of clients' satisfaction with payment cards is a significant factor in successful commercial eligibility of all banks. Not only are the debit cards a product but also a medium for advertisement and client's satisfaction. Therefore the investigation of overall customer satisfaction with payment cards and services is very important. The assessment of one scientific assumption and two hypotheses in this field is important and meaningful.

SA1: The overall level of customer satisfaction with payment cards will be over 70 %. SA1 has been proved. In our research, we have found out that the overall level of customer satisfaction with payment cards was over 80.95 %.

H1: The determination of satisfaction of clients with payment cards by gender and achieved level of education is not statistically significant. H1 has been proved. We have found out that there are no statistically significant differences between respondents of different gender and levels of education.

H2: The determination of satisfaction of customers with payment cards by age is statistically significant. H2 has not been proven. We found out that the customers' satisfaction with payment cards is not significantly determined by their age.

**Tab. 2 - Type of banking payment cards used**

From the presented options, please choose the ones which you personally use or would like to use in the future.		In total	Gender		Age		Education level	
			Women	Men	Under 30 yrs. old	Over 30 years old	Primary and secondary	University

	p-value		0.92034		0.40654		0.26272	

*Source: created by authors.*

Based on our investigation of the aspect as to which payment cards are currently used by customers and which payment cards they want to use in the future, we have found out that the most significant share is yielded by debit cards (59.44 %) and credit cards (29.72 %). Despite the fact that our results from prepaid cards (Tab 1) show a 4.48 % share, their number is gradually increasing.

**Tab. 3 - Number of banking payment cards used**

How many payment cards do you have altogether? This includes credit cards, debit card and consumer loan cards. From the presented options, please choose the ones which you personally use or would like to use in the future.		In total	Gender		Age		Education level	
			Women	Men	Under 30 years. old	Over 30 years old	Primary and secondary	University
1 card		382	235	147	149	233	276	106
	p-value		0.00072		0.24604		0.000

As to the number of payment cards, most customers (59.13 %) hold just one card, especially women (61.51 %) and persons aged over 30 years (60.99 %). These facts give an assumption of further acquisition activities of banks in the field of payment cards.

**Tab. 4 - Factors influencing the customer selection of a credit card**

What influences you most when selecting a CREDIT card? List three criteria.		In total	Gender		Age		Education level	
			Women	Men	Under 30 years. old	Over 30 years old	Primary and secondary	University
Fees		457	237	220	165	292	272	185
	p-value		0.00086		0.00012		0.000

The most significant factor in payment cards lies in their price, i.e. in the fee charged for using the payment cards. As to age, as many as 63.89 % of clients aged over 30 years are influenced by the charges.

SA2: The most significant factor in client's decision on using credit cards are the fees, while the impact measure of this factor will be over 50 % In our research, the measure of the impact of fees charged by banks will be over 65 %.

Tab. 5 - Factors influencing the customer selection of a debit card

What influences you most when selecting a DEBIT card? List three criteria.	In total	Gender		Age		Education level		
		Women	Men	Under 30 yrs. old	Over 30 years old	Primary and secondary	University	
Fees		429	241	188	175	254	276	153
	p-value		0.92034		0.96012		0.69654

	p-value		0.92034		0.89656		0.98404	

Source: created by authors.

The choice of debit card is mostly influenced by charges while as many as 59.20 % of respondents aged over 30 years and 61.33 % of respondents with elementary and secondary levels of education select their debit card based on the fees charged by the banks.

SA3: The most significant factor in client's decision on using debit cards are the charges and card issuer, while the impact measure of this factor will be over 50 %. Our research will show that the measure of the impact of charges and bank that issued the payment card will be over 60 %.

## **5 DISCUSSION**

Satisfied customer is of major importance for current and future financial performance of commercial banks. Korauš (2011) states that a satisfied customer stays loyal to his bank while costs incurred by keeping an existent customer satisfied are five times lower than those incurred in the process of gaining a brand new customer. A loyal customer is willing to pay a higher price whereas for luring a satisfied customer away from the competitor means to reduce the price of bank's product by 30 %. A satisfied client represents a free form of advertising. He is more inclined to purchase more products from the bank. A satisfied customer gives positive feedback to banks' employees, which in turn becomes a source of their satisfaction and pride in their work and business.

The level of customers' satisfaction in banking business differs considerably from country to country. The most important reasons for switching to another bank includes an increase in fees, poor service and operational personnel errors (Titko & Lace, 2010), lack of interest in solving clients' problems and high price policy (Belás et al., 2013b).

Our current research has confirmed these trends. The overall level of customers' satisfaction is comparable to the situation on European banking market. Clients feel low level of interest in solving their financial issues and high price policies of the bank. Banks also do not use the proper form of their sales opportunities, because only 33 % of respondents in our research have confirmed that employees of the branch often offer interesting products (53 % of respondents said that employees in the branch rarely offer products and 14 % of clients said that a banks has never offered an interesting products at all). This trend may also have implications on the cross-selling index. According to our findings, the average value of this index is 2.23. This number gives an indication of great sales opportunities for commercial banks in Slovakia, because a normal consumer needs objectively more banking products such as: current account for payment needs, credit card for regular purchases, savings account for the need to cover future risks and mortgages for provide housing or some investment products.

Tesfom and Birch (2011) suggest that young and older bank customers differ significantly in their perception of switching barriers: relational benefits, switching costs, availability and attractiveness of alternatives, service recovery and duration of time they intend to keep their relationship with their banks. According to the authors, older costumers are more satisfied with services than young clients who also prefer modern distribution channels and possibility of several alternatives. This research has been conducted in USA.

Our research has not confirmed the fact that the overall customers' satisfaction with provided services depends on age, gender, or education level of banks' clients. Our research has shown some differences between perceptions of selected social groups. For example when comparing young clients with old ones, the former surprisingly considered the poor availability of the branch as an important reason for their dissatisfaction and are less sensitive to the price of products and services. Compared to men, women are more sensitive to the

price and mode of operation in the branch. University graduates were more critical of banks and stated that the possibility to e-banking usage is the most important reason for their satisfaction.

These results indicate that attitudes of retail consumers differ from country to country. They determine the current situation on banking market and may have different objective preferences on traditional, historical, cultural, moral and political grounds. In this context, it is appropriate to conduct such studies on regional markets.

## 6 CONCLUSIONS

The results of our research have confirmed the validity of the first scientific assumption. Values of testing criteria have shown that the overall level of customer satisfaction with bank payment cards is over 70 %.

The first hypothesis has been confirmed. The overall customer satisfaction with bank payment cards is not statistically significant as to gender and achieved education level. We found that there were no statistically significant differences between genders and respondents with different levels of education.

The second hypothesis has been not confirmed. We found that the customer satisfaction with bank payment cards is not statistically significant as to age.

The research has confirmed the validity of the second scientific assumption, namely that in our research the measure of the impact of fees is over 65 %. Mostly affected clients by this factor are those aged over 30 years.

The third scientific assumption has been confirmed. The measure of the impact of fees in our research is over 60 %. This factor affects women significantly more than men; younger clients are less affected than older ones are. These findings can be interpreted as a fact that money saving belongs to major priorities of clients. The research has also shown that the sensitivity over bank payment cards is higher in women. This can be related to their feature of being more economical than men as a result of their high sense of responsibility toward family finances.

## **APPLIED MACHINE LEARNING PREDICTIVE MODELLING IN REGIONAL SPATIAL DATA ANALYSIS PROBLEM**

*Martin Kovářik, Radek Benda*

### **Abstract**

Urban and Regional Studies deal with large tables of spatial data obtained from censuses and surveys. It is necessary to simplify the huge amount of detailed information in order to extract the main trends. The main aim of this article is to present and compare machine learning models in spatial data analysis problem. As an example of spatial data modelling we draw upon public-domain data about California housing values. We use a variety of regression modelling techniques, showing how additional information about location (longitude and latitude) can contribute to the analysis. The data comprise observations of housing values, economic covariates, and longitude and latitude. We follow Pace and Barry (1997) in defining response and explanatory variables for a linear regression model.

## **1 INTRODUCTION**

Machine learning is a scientific discipline that explores the construction and study of algorithms that can learn from data. Such algorithms operate by building a model based on inputs and using that to make predictions or decisions, rather than following only explicitly programmed instructions.

Machine learning can be considered a subfield of computer science and statistics. It has strong ties to artificial intelligence and optimization, which deliver methods, theory and application domains to the field. Machine learning is employed in a range of computing tasks where designing and programming explicit, rule-based algorithms is infeasible. Example applications include spam filtering, optical character recognition (OCR), search engines and computer vision. Machine learning is sometimes conflated with data mining, although that focuses more on exploratory data analysis. Machine learning and pattern recognition „can be viewed as two facets of the same field“.

In 1959, Arthur Samuel defined machine learning as a "Field of study that gives computers the ability to learn without being explicitly programmed" (Simon, 2013).

Tom M. Mitchell provided a widely quoted, more formal definition: "A computer program is said to learn from experience  $E$  with respect to some class of tasks  $T$  and performance measure  $P$ , if its performance at tasks in  $T$ , as measured by  $P$ , improves with experience  $E$ " (Mitchell, 1997).

This definition is notable for its defining machine learning in fundamentally operational rather than cognitive terms, thus following Alan Turing's proposal in Turing's paper "Computing Machinery and Intelligence" that the question "Can machines think?" be replaced with the question "Can machines do what we (as thinking entities) can do?"

Statistical learning refers to a vast set of tools for understanding data. These tools can be classified as supervised or unsupervised. Broadly speaking, supervised statistical learning

involves building a statistical model for predicting, or estimating, an output based on one or more inputs. Problems of this nature occur in fields as diverse as business, medicine, astrophysics, and public policy. With unsupervised statistical learning, there are inputs but no supervising output; nevertheless we can learn relationships and structure from such data.

This contribution introduces application of machine learning models into spatial data analyses problem. Spatial analysis is a set of techniques for analyzing spatial data. The results of spatial analysis are dependent on the locations of the objects being analyzed. Software that implements spatial analysis techniques requires access to both the locations of objects and their attributes. Spatial statistics extends traditional statistics to support the analysis of geographic data. It provides techniques to describe the distribution of data in the geographic space (descriptive spatial statistics), analyse the spatial patterns of the data (spatial pattern analysis), identify and measure spatial relationships (spatial regression), and create a surface from sampled data (spatial interpolation, usually categorized as geostatistics).

## **2 LITERATURE REVIEW**

Though the term statistical learning is fairly new, many of the concepts that underlie the field were developed long ago. At the beginning of the nineteenth century, Legendre and Gauss published papers on the method of least squares, which implemented the earliest form of what is now known as linear regression. The approach was first successfully applied to problems in astronomy. Linear regression is used for predicting quantitative values, such as an individual's salary. In order to predict qualitative values, such as whether a patient survives or dies, or whether the stock market increases or decreases, Fisher proposed linear discriminant analysis in 1936. In the 1940s, various authors put forth an alternative approach, logistic regression. In the early 1970s, Nelder and Wedderburn (1972) coined the term generalized linear models for an entire class of statistical learning methods that include both linear and logistic regression as special cases. By the end of the 1970s, many more techniques for learning from data were available. However, they were almost exclusively linear methods, because fitting non-linear relationships was computationally infeasible at the time. By the 1980s, computing technology had finally improved sufficiently that non-linear methods were no longer computationally prohibitive. In mid 1980s Breiman, Friedman, Olshen and Stone (1984) introduced classification and regression trees, and were among the first to demonstrate the power of a detailed practical implementation of a method, including cross-validation for model selection. Hastie and Tibshirani (1986) coined the term generalized additive models in 1986 for a class of non-linear extensions to generalized linear models, and also provided a practical software implementation. Since that time, inspired by the advent of machine learning and other disciplines, statistical learning has emerged as a new subfield in statistics, focused on supervised and unsupervised modeling and prediction. In recent years, progress in statistical learning has been marked by the increasing availability of powerful and relatively user-friendly software, such as the popular and freely available R system. This has the potential to continue the transformation of the field from a set of techniques used and developed by statisticians and computer scientists to an essential toolkit for a much broader community.

Machine learning tasks are typically classified into three broad categories, depending on the nature of the learning "signal" or "feedback" available to a learning system. These are: (Russell and Norvig, 2003)

- Supervised learning. The computer is presented with example inputs and their desired outputs, given by a "teacher", and the goal is to learn a general rule that maps inputs to outputs.

- Unsupervised learning, no labels are given to the learning algorithm, leaving it on its own to find structure in its input. Unsupervised learning can be a goal in itself (discovering hidden patterns in data) or a means towards an end.
- In reinforcement learning, a computer program interacts with a dynamic environment in which it must perform a certain goal (such as driving a vehicle), without a teacher explicitly telling it whether it has come close to its goal or not. Another example is learning to play a game by playing against an opponent. (Bishop, 2006), (Wernick et al., 2010)

Between supervised and unsupervised learning is semi-supervised learning, where the teacher gives an incomplete training signal: a training set with some (often many) of the target outputs missing. Transduction is a special case of this principle where the entire set of problem instances is known at learning time, except that part of the targets are missing.

Among other categories of machine learning problems, learning to learn learns its own inductive bias based on previous experience. Developmental learning, elaborated for robot learning, generates its own sequences (also called curriculum) of learning situations to cumulatively acquire repertoires of novel skills through autonomous self-exploration and social interaction with human teachers, and using guidance mechanisms such as active learning, maturation, motor synergies, and imitation.

Spatial analysis confronts many fundamental issues in the definition of its objects of study, in the construction of the analytic operations to be used, in the use of computers for analysis, in the limitations and particularities of the analyses which are known, and in the presentation of analytic results. Many of these issues are active subjects of modern research.

Common errors often arise in spatial analysis, some due to the mathematics of space, some due to the particular ways data are presented spatially, some due to the tools which are available. Census data, because it protects individual privacy by aggregating data into local units, raises a number of statistical issues. The fractal nature of coastline makes precise measurements of its length difficult if not impossible. A computer software fitting straight lines to the curve of a coastline, can easily calculate the lengths of the lines which it defines. However these straight lines may have no inherent meaning in the real world, as was shown for the coastline of Britain.

These problems represent a challenge in spatial analysis because of the power of maps as media of presentation. When results are presented as maps, the presentation combines spatial data which are generally accurate with analytic results which may be inaccurate, leading to an impression that analytic results are more accurate than the data would indicate (Monmonier, 1996).

Spatial dependency is the co-variation of properties within geographic space: characteristics at proximal locations appear to be correlated, either positively or negatively. Spatial dependency leads to the spatial autocorrelation problem in statistics since, like temporal autocorrelation, this violates standard statistical techniques that assume independence among observations. For example, regression analyses that do not compensate for spatial dependency can have unstable parameter estimates and yield unreliable significance tests. Spatial regression models (see below) capture these relationships and do not suffer from these weaknesses (Kovarik, 2013), (Kovarik, Sarga and Klimek, 2015). It is also appropriate to view spatial dependency as a source of information rather than something to be corrected. (De Knegt et al., 2010)

Locational effects also manifest as spatial heterogeneity, or the apparent variation in a process with respect to location in geographic space. Unless a space is uniform and boundless, every location will have some degree of uniqueness relative to the other locations. This affects the

spatial dependency relations and therefore the spatial process. Spatial heterogeneity means that overall parameters estimated for the entire system may not adequately describe the process at any given location.

Alfons (2013a) provides cross-validation tools, which are useful in conducting benchmark studies as illustrated in this contribution. Benchmark studies, also known as statistical simulations, may be conducted within special packages designed for this type of research (Alfons 2013b; Alfons, Templ, and Filzmoser 2013).

Cressie (1993) and Lloyd (2010) provide an overview of methods in spatial data analysis. Spatially weighted regression can be especially useful in this domain of application (Fotheringham, Brunsdon, and Charlton 2002). Bivand, Pebesma, and Gómez-Rubio (2008), Bivand (2013), and Bivand and Yu (2013) review relevant software for spatial data modelling and geographically weighted regression.

Cressie and Wikle (2011) introduce the emerging area of spatio-temporal modelling. Spatio-temporal models are used in weather forecasting and in the study of global climate trends. They are used for research in spatial epidemiology, criminology, transportation, and logistics. We expect that spatio-temporal models will be utilized much more extensively in marketing analytics and predictive analytics in general as mobile data about consumers become more widely available. Cressie and Wikle (2011) describe spatio-temporal modelling as the next modelling frontier. Spatio-temporal models are, by definition, hierarchical model, typically Bayesian hierarchical models. Software for spatio-temporal modelling is available for the R programming environment (Pebesma 2013).

### **3 USED METHODS**

Quantitative and simulation methods was used for the issue solution. When solving these research problems methods are adequate to issues and objectives – a combination of quantitative and simulation methods of research. Machine learning models with 10-fold cross-validation used in processing the results are based on the experience of the authors. Below is shown some of used models in simulation study in very short description.

#### **3.1 Linear Regression**

The objective of ordinary least squares linear regression is to find the plane that minimizes the sum-of-squared errors (SSE) between the observed and predicted response:

$$SSE = \sum_{i=1}^n (y_i - \hat{y}_i)^2, \quad (1)$$

where  $y_i$  is the outcome and  $\hat{y}_i$  is the model prediction of that sample's outcome. Mathematically, the optimal plane can be shown to be

$$(X^T X)^{-1} X^T y, \quad (2)$$

where  $\mathbf{X}$  is the matrix of predictors and  $y$  is the response vector. Previous equation (1) is also known as  $\hat{\beta}$  ("beta-hat") in statistical texts and is a vector that contains the parameter estimates or coefficients for each predictor. This quantity (1) is easy to compute, and the coefficients are directly interpretable. Making some minimal assumptions about the distribution of the residuals, it is straightforward to show that the parameter estimates that minimize SSE are the ones that have the least bias of all possible parameter estimates

(Graybill, 1976). Hence, these estimates minimize the bias component of the bias-variance trade-off.

### **3.2 Regression Trees**

Tree-based models consist of one or more nested if-then statements for the predictors that partition the data. Basic regression trees partition the data into smaller groups that are more homogenous with respect to the response. To achieve outcome homogeneity, regression trees determine:

- The predictor to split on and value of the split
- The depth or complexity of the tree
- The prediction equation in the terminal nodes

In this section, we focus on techniques where the model in the terminal nodes are simple constants. There are many techniques for constructing regression trees. One of the oldest and most utilized is the classification and regression tree (CART) methodology of Breiman et al. (1984). For regression, the model begins with the entire data set,  $S$ , and searches every distinct value of every predictor to find the predictor and split value that partitions the data into two groups ( $S_1$  and  $S_2$ ) such that the overall sums of squares error are minimized:

$$SSE = \sum_{i \in S_1} (y_i - \bar{y}_1)^2 + \sum_{i \in S_2} (y_i - \bar{y}_2)^2, \quad (3)$$

where  $\bar{y}_1$  and  $\bar{y}_2$  are the averages of the training set outcomes within groups  $S_1$  and  $S_2$ , respectively. Then within each of groups  $S_1$  and  $S_2$ , this method searches for the predictor and split value that best reduces SSE. Because of the recursive splitting nature of regression trees, this method is also known as recursive partitioning.

### **3.3 Random Forests**

As illustrated with the solubility data, bagging trees (or any high variance, low bias technique) improves predictive performance over a single tree by reducing variance of the prediction. Generating bootstrap samples introduces a random component into the tree building process, which induces a distribution of trees, and therefore also a distribution of predicted values for each sample. The trees in bagging, however, are not completely independent of each other since all of the original predictors are considered at every split of every tree. One can imagine that if we start with a sufficiently large number of original samples and a relationship between predictors and response that can be adequately modelled by a tree, then trees from different bootstrap samples may have similar structures to each other (especially at the top of the trees) due to the underlying relationship. This characteristic is known as tree correlation and prevents bagging from optimally reducing variance of the predicted values. Despite taking bootstrap samples, each tree starts splitting on the number of carbon atoms at a scaled value of approximately 3.5. The second level splits vary a bit more but are restricted to both of the surface area predictors and molecular weight. While each tree is ultimately unique-no two trees are exactly the same — they all begin with a similar structure and are consequently related to each other. Therefore, the variance reduction provided by bagging could be improved. For a mathematical explanation of the tree correlation phenomenon, see Hastie et al. (2008). Reducing correlation among trees, known as de-correlating trees, is then the next logical step to improving the performance of bagging. From a statistical perspective, reducing correlation among predictors can be done by adding randomness to the tree construction process. After Breiman unveiled bagging, several authors tweaked the algorithm by adding

randomness into the learning process. Because trees were a popular learner for bagging, Dietterich (2000) developed the idea of random split selection, where trees are built using a random subset of the top  $k$  predictors at each split in the tree. Another approach was to build entire trees based on random subsets of descriptors (Ho, 1998; Amit and Geman, 1997). Breiman (2000) also tried adding noise to the response in order to perturb tree structure. After carefully evaluating these generalizations to the original bagging algorithm, Breiman (2001) constructed a unified algorithm called random forests. A general random forests algorithm for a tree-based model can be implemented as shown in figure 1.

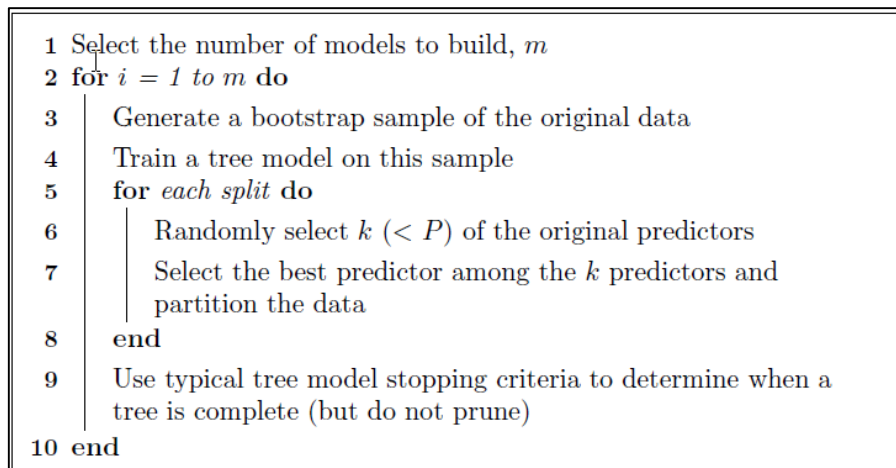

Fig. 1 – Basic Random Forests algorithm. Source: Kuhn and Johnson, 2013.

### 3.4 Support Vector Machines

Support vector machines are a class of statistical models first developed in the mid-1960s by Vladimir Vapnik. In later years, the model has evolved considerably into one of the most flexible and effective machine learning tools available, and Vapnik (2010) provides a comprehensive treatment. Here we touch on similar concepts from SVM for regression and layout the case for classification. Consider the enviable problem shown in the left panel of figure 2 where two variables are used to predict two classes of samples that are completely separable. As shown on the left, there are a multitude (in fact an infinite) number of linear boundaries that perfectly classify these data. Given this, how would we choose an appropriate class boundary? Many performance measures, such as accuracy, are insufficient since all the curves would be deemed equivalent. What would a more appropriate metric be for judging the efficacy of a model? Vapnik defined an alternate metric called the *margin*. Loosely speaking, the margin is the distance between the classification boundary and the closest training set point.

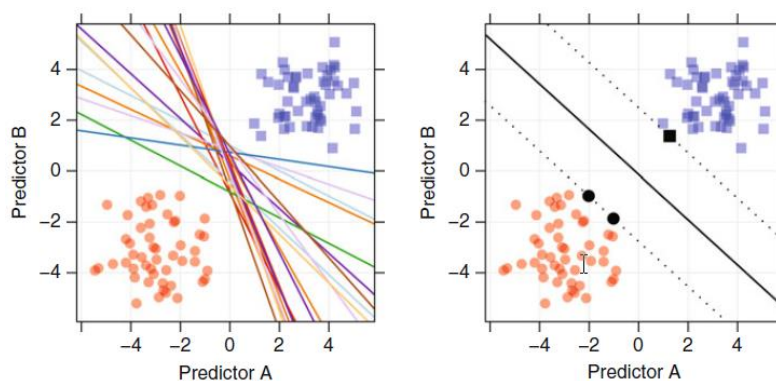

Fig. 2 – *Left*: A data set with completely separable classes. An infinite number of linear class boundaries would produce zero errors. *Right*: The class boundary associated with the linear maximum margin classifier. The solid black points indicate the support vectors. Source: Kuhn and Johnson, 2013.

For example, the right-hand panel of figure 2 shows one possible classification boundary as a solid line. The dashed lines on both sides of the boundary are at the maximum distance from the line to the closest training set data (equidistant from the boundary line). In this example the three data points are equally closest to the classification boundary and are highlighted with solid black symbols. The margin defined by these data points can be quantified and used to evaluate possible models. In SVM terminology, the slope and intercept of the boundary that maximize the buffer between the boundary and the data is known as the maximum margin classifier.

### 3.5 Cubist Model

Cubist is a rule-based model that is an amalgamation of several methodologies published some time ago (Quinlan 1987, 1992, 1993) but has evolved over this period. Previously, Cubist was only available in a commercial capacity, but in 2011 the source code was released under an open-source license. At this time, the full details of the current version of the model became public. Our description of the model stems from the open-source version of the model. The implementation of Cubist uses Manhattan (a.k.a. city block) distances to determine the nearest neighbors. Also, neighbors are only included if they are “close enough” to the prediction sample. To filter the neighbors, the average pairwise distance of data points in the training set is used as a threshold. If the distance from the potential neighbor to the prediction samples is greater than this average distance, the neighbor is excluded (Kuhn and Johnson, 2013).

### 3.6 *k*-Fold Cross-Validation

The samples are randomly partitioned into *k* sets of roughly equal size. A model is fit using the all samples except the first subset (called the first *fold*). The held-out samples are predicted by this model and used to estimate performance measures. The first subset is returned to the training set and procedure repeats with the second subset held out, and so on. The *k* resampled estimates of performance are summarized (usually with the mean and standard error) and used to understand the relationship between the tuning parameter(s) and model utility. The cross-validation process with *k* = 3 is depicted in figure 3 (Kuhn and Johnson, 2013).

Fig. 3 – A schematic of threefold cross-validation. Twelve training set samples are represented as symbols and are allocated to three groups. These groups are left out in turn as models are fit. Performance estimates, such as the error rate or  $R^2$  are calculated from each set of held-out samples. The average of the three performance estimates would be the cross-

validation estimate of model performance. In practice, the number of samples in the held-out subsets can vary but are roughly equal size. Source: Kuhn and Johnson, 2013.

#### **4 SOLUTION**

As an example of spatial data modelling we draw upon public-domain data about California housing values. We use a variety of regression modelling techniques, showing how additional information about location (longitude and latitude) can contribute to the analysis. The data comprise observations of housing values, economic covariates, and longitude and latitude. We follow Pace and Barry (1997) in defining response and explanatory variables for a linear regression model. Original models and computed variables are shown below. For our purposes we used data set (Pace and Barry, 1997) which is available from the Carnegie-Mellon StatLib repository (see the reference no 36). It consists of aggregated data from each of 20,460 neighborhoods (1990 census block groups) in California.

We select a subset of 1,206 block groups, focusing on the region around San Diego, further dividing the data into 803 training observations, and 403 test observations.

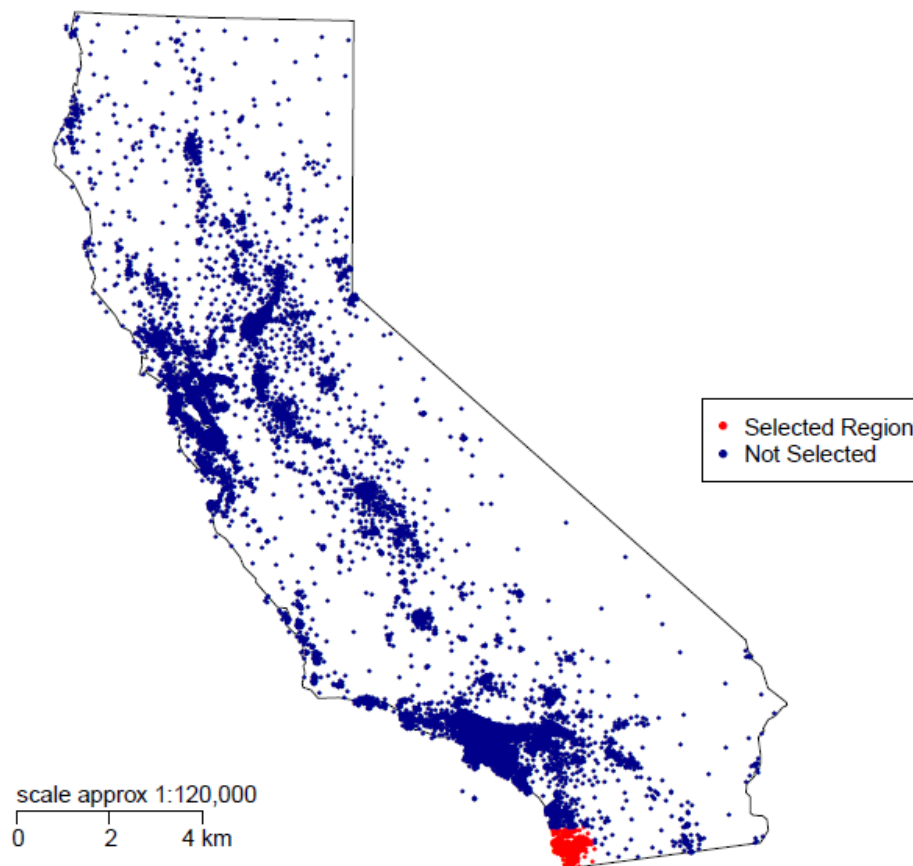

Fig. 4 – Spatial map of selected region. Source: Own work in R.

Relationships between pairs of variables in this problem are shown in the correlation heat map in figure 5, which orders explanatory variables by their correlation with the response variable used in the Pace and Barry (1997) model, the log median housing value of homes in the block groups (in hundreds of thousands of dollars). From the correlation heat map we can see the importance of income in explaining housing values. Note the apparent censoring for the log median value and age of houses. Original database and computed variables are shown below. Pace and Barry (1997) model for baseline for comparisons:

$$\begin{aligned} \log(\text{value}) = & \text{income} + \text{income}^2 + \text{income}^3 + \\ & + \log(\text{age}) + \log(\text{pc\_rooms}) + \log(\text{pc\_bedrooms}) + , \\ & + \log(\text{pop\_hh}) + \log(\text{hh}) \end{aligned} \quad (4)$$

where value is median house value (\$100,000), income is median income (\$10,000), age is housing median age (years), rooms are total rooms, bedrooms are total bedrooms, pop is population, hh is households, latitude is latitude, longitude is longitude, log(pc\_rooms) is log per capita rooms: log(total rooms / population), log(pc\_bedrooms) is log per capita bedrooms: log(bedrooms / population), log(pop\_hh) is log population per household and log(hh) is log households. For comparison lets look at a simple model with the original variables:

$$\log(\text{value}) = \text{income} + \text{age} + \text{rooms} + \text{bedrooms} + \text{pop} + \text{hh}. \quad (5)$$

And for comparison lets look at a full model with the transformation of original variables:

$$\begin{aligned} \log(\text{value}) = & \text{income} + \text{age} + \text{rooms} + \\ & + \text{bedrooms} + \text{pop} + \text{hh} + \log(\text{pc\_rooms}) + . \\ & + \log(\text{pc\_bedrooms}) + \log(\text{pop\_hh}) \end{aligned} \quad (6)$$

A review of the correlation heat map in figure 5 also reveals strong correlations among predictors. Correlations among predictors is called *multicollinearity* and is a special concern of modellers working in regression contexts (Belsley, Kuh, and Welsch, 1980). Additional issues are raised by a review of the scatter plot matrix in figure 6.

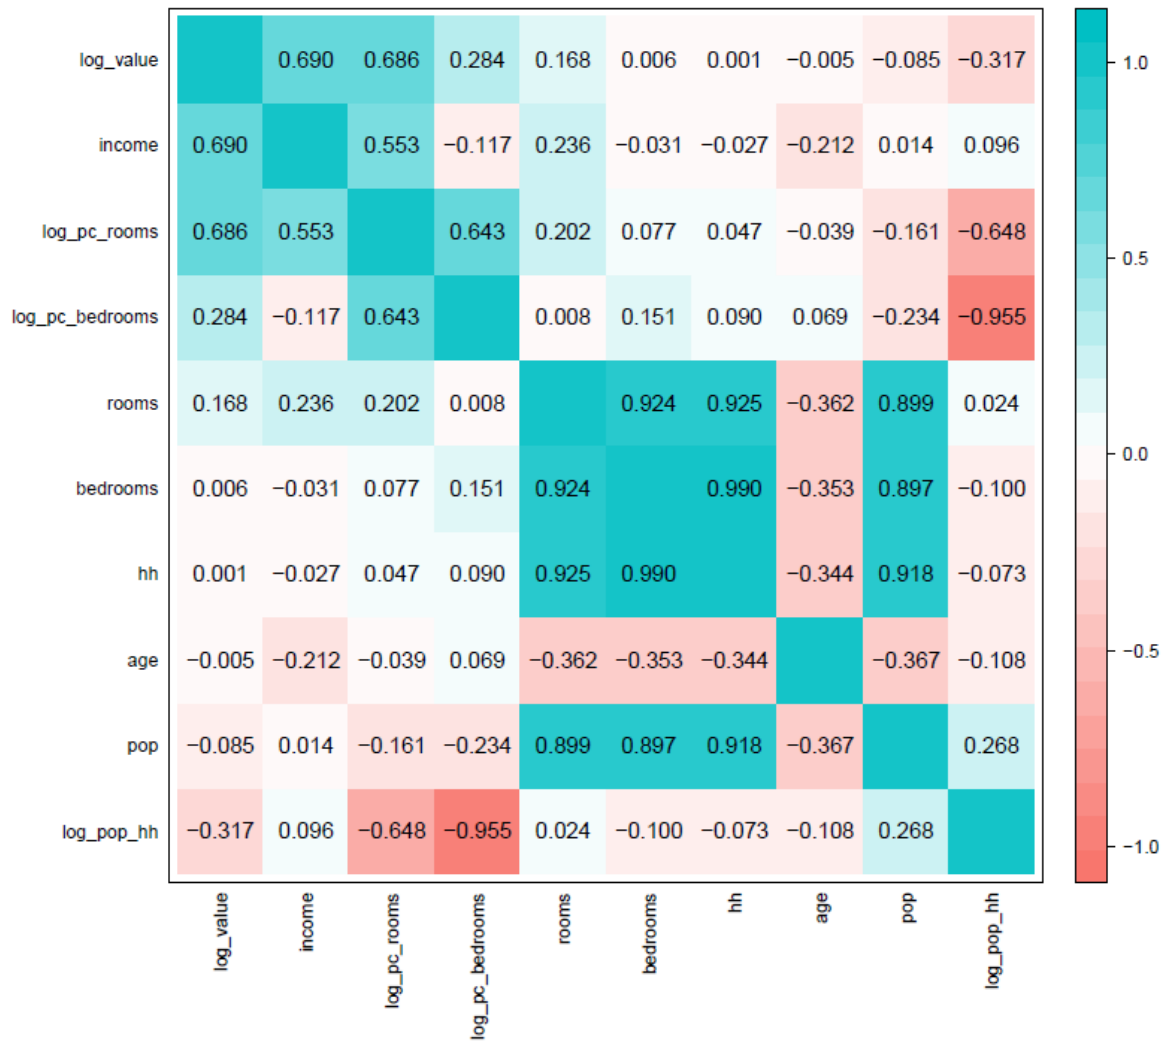

Fig. 5 – California Housing Data: Correlation Heat Map for the Training Data.  
Source: Own work in R.

The standard linear regression for the training data using the Pace and Barry (1997) model is not shown here, but this model, which will serve as a baseline for comparing other regression models in this problem, explains 45.4 percent of response variance in the test set and RMSE is 0.339. The response in this problem is the natural logarithm of median home value in the block group. We note that multicollinearity is introduced into this problem by Pace and Barry’s (1997) use of income, squared income, and cubed income in the linear predictors. We note as well that, in tests of hypotheses about regression coefficients, the model assumes independent observations. This is a questionable assumption given that observations are expected to be spatially autocorrelated.

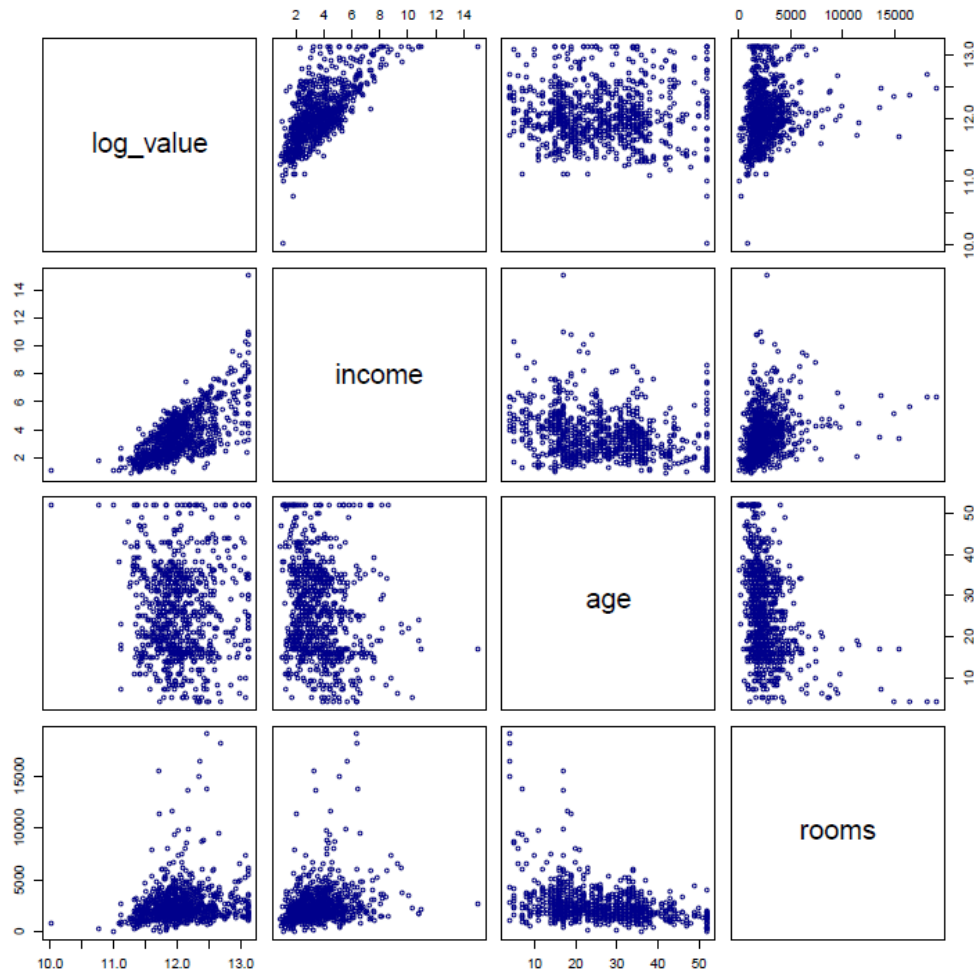

Fig. 6 – California Housing Data: Scatter Plot Matrix of Selected Variables.  
Source: Own work in R.

These data provide an opportunity to examine various regression models. We begin with tree-structured regression using the original set of variables, ignoring the added variables from Pace and Barry (1997). This model fits the test data well, explaining 45.4 percent of response variance, which is a poor job in predicting. If we include the full set of variables as input to tree-structured regression, we do better, with the model explaining 58.8 percent of response variance in the test set, and RMSE is much lower.

A random forest fit to these data, using the original explanatory variables only, performs very well on the test set, explaining 65.9 percent of response variance and RMSE is 0.259. Predictive models with spatial data may be improved by adding a spatial component. All other things being equal, we expect that observations close together in space will be more similar to one another than observations separated by greater distances. In other words, there will be spatial autocorrelation. We expect that this will be true for housing values as well as for variables being used to explain housing values. Spatial data models use information about observations location in space (longitude and latitude). Geographically weighted regression is especially useful for working with problems like the Californian housing study. When we fit a geographically weighted regression model to the data for the California housing study, we are able to explain 62.6 percent of response variability in the test set and RMSE is 0.27 and 71.6 percent in the training set. To improve further on the accuracy of predictive models for this problem, we use the two best performing models in the test set (random forests and geographically weighted regression) to create a hybrid model. In particular, we compute the

average of the predictions from the random forests and geographically weighted regressions. The resulting SVM and GBR model for all predictors outperforms all other models tested on the test set, explaining 69.78 percent of response variance and 65.76, respectively. These two models are the most suitable for further prediction because of their stability in difference between training and test R-squared and RMSE criteria. A summary of the findings is shown in table 1.

The value of a model lies in the quality of its predictions. Regression and spatial data models are important in predicting housing values. They are also important in location-based demand estimation, sales forecasting, and site selection research. Traditional theory-based, data-adaptive, and hybrid methods may be employed, as we have seen in working with the California housing study.

Fig. 7 – Model Comparison by 10-fold Cross-Validation for Test Data.  
Source: Own work in R.

Working with block groups in the California housing study, we implicitly take location into account because response and explanatory variables are linked to the observational unit—the block group location. We can do more with spatially-referenced data such as these. Because we have information about longitude and latitude, we can use distances between observational units to build nearest-neighbour predictors, and we can use distance-referenced explanatory variables in predictive models.

Tab. 1 – The Results of Models Comparison: Own work in R.

Model	Training Data Set		Test Data Set	
	R <sup>2</sup>	RMSE	R <sup>2</sup>	RMSE
LinearRegression	0.548	0.299	0.454	0.339
Regression Trees	0.548	0.299	0.454	0.339
Regression Trees Full	0.616	0.273	0.588	0.288

Random Forest	0.642	0.263	0.564	0.295
Random Forest Full	0.678	0.249	0.660	0.260

Cubist Model Full	0.676	0.251	0.658	0.263

We use the proportion of response variance accounted for as a criterion for evaluating regression performance in the California housing study. This criterion is also known as the coefficient of determination or R-squared. It varies from zero to one with higher numbers indicating higher goodness of fit and better models. We compute its value in the test set by squaring the correlation of observed and predicted response values. Proportion of response variance is an easy concept for managers to understand, and this index of goodness of fit takes values from zero to one in all studies.

## 5 CONCLUSION

The main aim of this article was to present and compare machine learning models in spatial data analysis problem. As an example of spatial data modelling we drew upon public-domain data about California housing values. We used a variety of regression modelling techniques, showing how additional information about location (longitude and latitude) can contribute to the analysis. The data comprise observations of housing values, economic covariates, and longitude and latitude. We followed Pace and Barry (1997) in defining response and explanatory variables for a linear regression model. For the prediction of California housing values we chose SVM and GBR model with highest R-squared in training and test set and quite stable RMSE in both data sets.

## **EFFECTIVE CORPORATE TAXATION AND STATUTORY TAX RATE**

*Ivana Košťuríková*

### **Abstract**

Corporate taxes have a significant impact on the company's decisions about their business activities in the country. Due to the corporate taxation a lot of companies moved from countries with high rates to low-cost tax destinations. A gradual decline in the income tax of corporations has occurred in Europe over the past decades. This fact affected behaviour of advanced economies, which were forced to increase or at least maintain competitiveness of their country in the fight for foreign investors with the adjacent Central European or East European countries. In this respect, the efforts to maintain significant domestic companies on its territory and prevent from their leave to more favourable destinations in terms of tax and to the countries with cheap labour force, which include also the East European countries, has become the strategy of the West European countries. On the contrary, the East European countries attempted to attract these foreign companies to conduct business in these countries. An effective corporate tax rate could prove to be a convenient comparative value for comparison of corporate taxation. This rate does not include only the amount of the statutory tax rate on corporate income but also other aspects of tax systems determining the total amount of effectively paid taxes.

### **1 INTRODUCTION**

The enlargement of the European Union and the globalisation process also substantially affect taxation systems and fiscal policy in the individual countries (Reodano, 2007). In the sphere of direct taxes the important external factor is the tax competition between single countries and that is also in the frame of the expanded European Union (Baldwin&Krugman, 2004). It depends on historical development of each country, and also on economic, political, and, last but not least, philosophical opinions, how the structure and content of the tax system will be influenced. It is important for the state to pursue a favourable tax policy to ensure support to all taxpayers and thus to ensure competitiveness of the state and development of the society.

As far as decisions of corporate management are concerned, the taxation system is one of the decisive factors. The taxation environment in which a company operates affects the amount and distribution of the disposable profit, a selection of optimal financial and asset structure, investments etc., which is directly related to the financial position of the company, its individual activities and affects also production factors and for foreign investors the amount of burden is one of the significant factors affecting the selection of the place of business.

According to the comparison of legal entities income tax, decreasing tax burden for firms has been showed unambiguously in the last decade. However, apart from that, economic behaviour of companies, in connection with positioning their capital abroad, reacts on comparability of tax conditions in single countries. According to Šíroký (2008), appropriate adjustment of corporate tax rate may stimulate businesses for more economic activity.

### 1.1 Aim and methodology

The aim of this paper is to evaluate the effective taxation of corporations which can be expressed using either the effective average tax rate (EATR) or implicit corporate tax rate (ICTR) and using simple regression analysis to examine the dependence of the effective corporate taxation on the statutory tax rate on corporate income. Equation of selective regression function that has the form:

$$\hat{y} = b_0 + b_1x \quad (1)$$

where:  $b_0, b_1$  - selective (empirical) regression parameters,

$x$  - statutory tax rate on corporate income (independent variable),

$\hat{y}$  - effective or implicit tax rate on corporate income (dependent variable),

presents an approximation of the entered values where the coefficients are determined by the method of least squares, so that the sum of squared deviations of the original values from obtained model would be minimum. The  $R^2$  index expresses the degree of reliability of the calculated estimate of the development.

## 2 TAX REVENUES

Tax systems are dependent on a number of factors, which affect in mutual circumstances fulfilment of the basic principles and functions of taxes (Smith, 2007). There has not been a lot of changes in requirements for a good tax system and individual taxes since the Adam Smith's time (Kubátová, 2010). The good tax system cannot simultaneously fulfil all requirements as they are in conflict with each other (Vančurová&Láchová, 2010). The structure as well as amount of taxes is primarily subject to economic factors, such as the economic growth, inflation rate, the extent of engagement of the economy in the international trade, sector and geographic structure as well as the workforce structure. The sector structure in connection with the extent of concentration of the economy, i.e. the proportion of corporations.

The government's choices of the corporate tax rate and public investment are interdependent (Gomes&Pouget, 2008). It is important to note that the proportion of corporate tax incomes in the total incomes from taxes grew until 2008 in spite of a fall in the statutory tax rates of legal persons, which was caused by tax competition. This fact was a result of extension of tax bases, progress of corporate business and other factors. However, this trend has changed as a result of the economic crisis. The development of the proportion of the tax from companies' profit in the total tax income is presented in the following table and figure (in Croatia case, all data are not available).

Fig. 1 – The proportion of the tax on corporations' profit in the total tax incomes in the years 2000 - 2012. Source: author by Taxation trends in European Union, 2014.

As we can see in the figure above, the share of corporate tax revenues in total tax revenues in the Czech Republic is significantly higher than the average value in the European Union. On the other hand, this tax revenue is still declining in our country unlike EU-28, where the value is around 7.5 %, and unlike EA-18, where a slight increase is even evident.

According to the statistics, the general dramatic fall in the statutory rates was not accompanied by a fall in tax payments proportionally with GDP, as it is apparent in the following table and figure.

Tab. 2 – The proportion of the tax on corporations' profits in GDP in the individual EU countries in the years 2000 - 2012. Source: Taxation trends in European Union, 2014.

### 3 STATUTORY TAXATION

In the Czech Republic, the income tax has showed a gradual fall, including the income tax of legal persons (corporations). This trend has been reflected across the European Union in the long term, but not in all countries. Therefore, differences between corporate tax rates have arisen when the lowest rates are in Bulgaria and Cyprus, both at the level of 10 %. On the other hand, the group of countries with the highest basic rates over 30 % includes Malta, France a Belgium.

The following figure shows the basic rate of corporate income tax in the individual countries of the European Union in 2013. It may be deduced from it that the Czech Republic is, with the rate of 19 %, below the EU average rate which is just under 22 %. The corporate tax rates at the same level of 19 % are both in Poland and Hungary. The same rate was in neighbouring Slovakia but it has proceeded the opposite direction than most of the EU countries and has increased this rate by 4 percentage points to 23 % in 2013 (Kozelský&Jedlička, 2013).

Fig. 3 – The basic tax rate on corporate income in the EU countries in 2013. Source: author by Kozelský&Jedlička, 2013.

Some states added the various surcharges or local rate to the basic tax rate. The Belgian basic corporate tax (33 %) is increased by 3% surcharge. In Luxembourg there is not only 7% surcharge but also the local rate in the amount of an additional 6.75 %. The additional local rates are used more in Hungary, Italy, France, Spain and Germany. The statutory income tax rates, which include not only basic tax rates, but also temporary or permanent additional taxes and reliefs, are shown in figure 4.

Fig. 4 – The top statutory tax rate on corporate income in 2014. Source: author by Taxation trends in European Union, 2014.

#### **4 EFFECTIVE TAXATION**

Different rules for setting corporate tax base and its amount, which are caused by individual tax legislations in the particular countries, also mean a substantial limitation for an objective comparison of tax burden for companies by statutory income tax rates in those countries. Consequently, statutory tax rate cannot serve as an impartial indicator for the purposes of mutual comparison of this burden in different states, and therefore economists had to come up with a new measure for effective taxation of corporations. This issue has extensively dealt with by Barrios, Nicodème and Fuentes (2014).

As Blechová (2014) claims, there exist three methods of determination of effective tax rates. These methods are coined as methods of backward macroeconomic view, backward microeconomic view and forward microeconomic view. The differences between macroeconomic and microeconomic approaches are determined by the applied data. The macroeconomic approach calculates effective tax rates of aggregated macroeconomic data contained in the national accounting of the individual states. On the contrary, microeconomic approaches calculate these rates from the financial statements of the individual companies containing either empirical data or data concerning the theoretical perspective. The differences between the approaches with backward and forward perspective are determined by the type of applied information. For estimation of tax burden of companies, approaches with backward view use ex-post data concerning the real life of companies, while the approaches with forward perspective use statutory characteristics of a tax system for determination of tax aspects concerning future business decisions of companies. Nicodème (2002) claims, using the micro backward-looking approach to compute effective tax rates there could be some concerns regarding domestic tax discrimination since some sectors and sizes enjoy significantly more favorable tax burdens.

#### 4.1 Effective average tax rate

The impact of taxation on the choice is measured by the proportion of total income taken in tax in each location. Devereux and Griffith (2003) proposed a measure of an effective average tax rate (EATR) to identify the effect of taxation on such discrete location choices.

Fig. 5 – The effective average tax rate in 2013. Source: author by Taxation trends in European Union, 2014.

Figure 5 shows the effective average tax rates in the individual EU Member States in 2013. In this year the lowest EATR was in Bulgaria (9 %). The biggest decrease of this rate occurred in this country, namely by 19.1 percentage points from 28.1 % in 2000. The significant decrease of the rate is also apparent in the Czech Republic from 23.6 % in 2000 to 16.6 % in 2013.

The forward-looking effective tax rates offer a convenient theoretical framework for summarising at a broad level the interaction of tax rules relating to capital investment. It should be noted that the indicator should be interpreted with caution, taking into account the assumptions related to the hypothetical investment as well as to the modelling detail of the tax systems.

#### 4.2 Implicit tax rate

Implicit corporate tax rate also appears to be an appropriate measure of comparison of effective corporate taxation. This tax rate takes into account not just the amount of the statutory tax rates from corporations' rates but also other aspects of taxation systems determining the total amount of effectively paid taxes. The implicit corporate tax rate is calculated as a ratio of the aggregated income taxes or from profits paid by corporations to the value of tax base, which is the corresponding potentially taxable base including these aggregated values: net operating profit/loss of non-financial and financial corporations, the difference between the received and paid interest, rent of lands, income from property insurance and dividends distributed by companies operating in the particular state and credited to non-financial and financial corporations, households, independent entrepreneurs and non-profit institutions, state authorities and the rest of the world (Blechová, 2010).

The following figure presents the implicit tax rate of corporations in some EU Member States in 2012. For other countries data are not available.

Fig. 6 – The implicit tax rate in 2012. Source: author by Taxation trends in European Union, 2014.

The implicit tax rate on corporate income did not change significantly in the Czech Republic in the years 2000 - 2012 and fluctuated around 21.5 % in 2012. In 2000 it was the lowest ICTR (24.5 %) of all Visegrad group countries when the highest implicit taxation was reached by corporations in Slovakia (40.2 %). In the neighbouring countries there was a gradual reduction of the implicit rate to below the level of implicit taxation in the Czech Republic (in Hungary from the rate of 34 % in 2000 to the rate of 10.6 % in 2012).

## 5 RESULTS

As already mentioned, the effective average tax rate and the implicit tax rate are appropriate criteria to compare the effective taxation of corporate income. The dependence of both rates on statutory corporate tax rate was examined by simple linear regression.

The figure 7 shows that the 99 % of EATR changes are explained by changing of statutory tax rate. The regression line was estimated using the least squares method, from which it can be deduced that an increase in the statutory corporate tax rate by 1 % results an increase in the effective average tax rate on average by 0.76 %.

Fig. 7 – Effective average tax rate depending on statutory tax rate. Source: author’s analysis.

To verify whether the regress model is indeed suitable for the data, first there were tested the individual parameters using the t-test. The statistical significance of the whole model was then verified using the F-test. Based on the results in tab. 3 and 4, it is clear, that statistically the both parameters (intercept and slope) are not significant. The regression model is suitable and can be used for the data.

Tab. 3 – Test of significance of regression parameters. Source: author’s analysis.

Parameter	Estimate	Standard Error	T Value	Prob. Level
Intercept ( $b_0$ )	3.693512924	0.589148592	6.269238307	2.88209E-05
Slope ( $b_1$ )	0.75843445	0.021487049	35.29728382	2.68701E-14

Tab. 4 – Test of the suitability of the regression model. Source: author’s analysis.

ANOVA	Df	Sum of Squares	Mean Square	F - Ratio Prob.	Level
Model	1	121.8644048	121.8644048	1245.898245	2.68701E-14
Error	13	1.271562319	0.097812486		
Total	14	123.1359671			

As shown in figure 8, the 81 % of ICTR changes are explained by changing of the statutory tax rate. The remaining approximately 19 % of changes are caused by other factors (mainly tax base construction and tax deduction).

Fig. 8 – Implicit tax rate depending on statutory tax rate. Source: author’s analysis.

Based on the result of regression coefficients test (tab. 5) it is clear that parameter  $b_0$  (intercept) is not statistically significant, on the other hand, the parameter  $b_1$  (slope) is. Test of suitability of the regression model (tab. 6) confirmed that the model is suitable and can be used for the data.

Tab. 5 – Test of significance of regression parameters. Source: author’s analysis.

Parameter	Estimate	Standard Error	T Value	Prob. Level

Total	16	222.4118539			

## 6 CONCLUSION

The tax system is expected to remain unchanged over the life of the investment. The impact of taxation depends on a number of features of the tax system, including the statutory tax rate, capital allowances, the treatment of foreign source income, wealth taxes paid by the company, as well as possibly the treatment at the corporate and personal level of dividends paid by the company, and wealth and capital gains taxes at the personal level.

Rates and development of corporate taxes in individual countries are carefully observed because their amounts are really important in corporate decision-making about the allocation of investment. The simplest alternative is the comparison of statutory corporate rates of income taxes. For its simplicity and easy availability of data, this comparison has been becoming the most commonly applied. Different rules for setting corporate tax base and its

amount, which are caused by individual tax legislations in the particular countries, are a substantial limitation for an objective comparison of tax burden for companies by statutory income tax rates in those countries. Consequently, for the purposes of the reciprocal international comparison, statutory tax rates are not quite an appropriate and objective indicator.

The instrument which removes the imperfect information capability of the basic or statutory tax rates is the implicit tax rate. It takes into account the tax base and the method (if any) by which the systems of corporate and personal income taxes are integrated. For comparison, companies can also use the effective average tax rate which is calculated by special methods.

## **PERSONALITY TYPES OF ENTREPRENEURS AND SELECTED ATTRIBUTES OF CREDIT RISK IN THE SME SEGMENT. A CASE STUDY FROM CZECH REPUBLIC AND SLOVAKIA**

*Ludmila Kozubíková, Přemysl Bartoš*

### **Abstract**

The aim of this article was to examine the relationship between personality characteristics and approach to the perception and management of credit risks. Based on the preferred personality qualities and knowledge the entrepreneurs have been included into two categories, namely they are artist-entrepreneurs and businessmen-laborers, also the differences in their entrepreneurial attitudes have been examined. Our results showed that there are differences in the attitudes of these two categories of entrepreneurs in approaching credit risk, where it was found out that the defined categories of business have different approaches to knowledge of credit conditions of commercial banks. According to the findings of our research, there are significant differences between defined types of businessmen while evaluating changes to the current approach of commercial banks in lending to SMEs in comparison to the pre-crisis period. The results of our study have showed a high degree of confidence of individual groups of entrepreneurs when evaluating their ability to manage financial risks in the company.

*Keywords: entrepreneurship, types of entrepreneurs, segment SME, credit risk*

## **1 INTRODUCTION**

Small and medium-sized enterprises play an important role in the economic system of any developed country.

The business environment of small and medium-sized companies varies considerably. In this context, Bilan (2013) states that ecological, economical, social and environmental problems, as well as challenges connected with developing of the consumers, make the companies concerned with existing level and quality of relationship between them and the society, their employees and their consumers.

In this context, it is clear that the issue of entrepreneurship in the small and medium-sized companies is very topical area of scientific research. Currently, great importance is given to research of personal and knowledge characteristics of people for business because many of the results that are mentioned below show the fact that to be an entrepreneur does not fit all the people and the business needs a specific properties. These properties may affect the approach to the assessment and management of business risks that significantly influence the success in business.

In our article there are examined the selected attributes of the credit risk of SMEs in relation to the defined personality types of entrepreneurs.

## **2 THEORETICAL BACKGROUND**

The business environment is determined by personality characteristics and motives of individual entrepreneurs. Business situations are often unique in their unpredictability,

complexity and changing requirements during the business process. Entrepreneurs must be capable to have the features of several personalities at once and as one person to demonstrate the ability to act as investors, inventors, accountants, dispute investigators, leaders, technologists, marketing specialists and top sellers. For this reason, the more knowledge and skills the entrepreneur is capable to demonstrate the better. (Frese, Gielnik, 2014)

According to Deáková, Drážovská, Grznárik and Kondášová (2010) the most important personal qualities for an entrepreneur are: courage, self-reliance, responsibility, determination, perseverance, proactive approach, creativity and scholarship in a particular area, where this businessman intends to do business.

Kvietok (2013) states, that decision to take on the business risk is symptomatic of a certain type of people. A significant part of the motivation to take risks in business follows from the success motivation. To achieve the set goals, successful people are willing to take on reasonable risks associated with feedback about the level of achieved results. Entrepreneurs are sort of being managed with an inner feeling, which means that they feel that their personal fate is the result of their own efforts. They are independent, autonomous, and rely on themselves, what are the characteristics of entrepreneurial personalities.

According to Beugelsdijk and Noorderhaven (2005), entrepreneurs differ from the general population and from paid employees in a lot of characteristics. They are more individually oriented; they have a greater individual responsibility and effort. In this context Omerzel and Kušce (2013) indicate that the inclination to take risks, self-efficacy and the need for independence are the most important factors affecting personal performance of the businessman.

According to Soininen, Martikainen, Puumalainen and Kyläheiko (2012) consider innovativeness, risk-taking and proactivity as essential characteristics of entrepreneurial orientation. According to Eggers, Kraus, Hughes, Laraway and Snyckerski (2013) to drive company to growth, the firm will need to deploy a strategy centred on entrepreneurial orientation or else risk stagnation. In this regard Lasagni (2012) indicates that her results show that innovation performance is higher in SMEs that are proactive in strengthening their relationships with innovative suppliers, users, and customers.

Moro and Fink (2012) state that the banks play an essential role in financing SMEs because these have more difficulties accessing equity on capital markets.

Important issue of SMEs is represented by financial gap because many of these companies have very limited access to external financial resources. (European Commission, 2011) This disadvantageous standings is partially compensated by national and regional policies (Grebeníček et al., 2013) and also by the policies of the European Union including cohesion policy, although the success of targeting the entrepreneurs in both countries varies (Hájek et al., 2014). In this context, Dierkes, Erner, Langer and Norden (2013) state that companies in small and medium sector are smaller, more informationally opaque, riskier, and more dependent on trade credit and bank loans. According to Canales and Nanda (2012) small businesses, and particularly young small businesses, have little internal cash flow to finance their operations and are also associated with significant asymmetric information.

In relationship to the features of the personality of the businessmen Mishra and Lalumiere (2011) in the results of their study show that personality characteristics such as impulsivity, search for sensation, low self-control may represent mechanisms through which the preferences of risk are manifested in the behavior. Risk-taking, respectively willingness to abandon already known and right ways and get down to the business with uncertain income should be important for achieving the objectives of the international level. The tendency to

seek high-risk situation is also associated with a tendency to be optimistic and perceive opportunities rather than threats in any situation (Dai, Maksimov, Gilbert, Fernhaber, 2014). A reasonable optimism is desired from the perspective of the development of the company. An excessive optimism may have harmful effects because entrepreneurs are making strategic errors or plunge into a large number of tasks at once (Frese, Gielnik, 2014).

Banks stated in their documents that there is a rule in the rating process: the smaller company, the more important soft information.

Moro and Fink (2012), Belás, Cipovová, Novák, and Polách (2012), Cipovová and Belás (2012) state that the econometric findings show that lending relationships cannot be reduced to facts and figures because, by leveraging strong relationships, trust can also support and increase the amount of other soft and hard information that the loan manager can access and, thus, help the loan manager to take decisions. In this context Belás and Polách (2011) state that models for credit risk measuring are representing tendency to exactly define complex economic processes using mathematical or statistical models. Such models in despite to sophisticated approach cannot and fail to express truly a complexity of economical system, determined by other important undefinable values, such as attitude, expectation, each economic entity preferences.

The document of European Commission (2006) states that in the research of McKinsey & Company, 75 % of the total number of medium and large-sized banks consider indebtedness of enterprises as the most important quantitative factor of internal rating. 50 % of banks give equal attention to the following indicators: liquidity and profitability. From wide range of possible qualitative factors, approximately 50 % of medium and large-sized banks give high or very high attention to the quality management of SME and to following factors such as: market situation of SME and its legal form. According to this document, qualitative factors have a bigger impact on the rating in the case of larger companies or larger loans. In the case of start-ups companies, weights of these factors on the overall rating represent approximately 60 %. In the case of companies with sufficiently long business history (minimum 2 years), weight of qualitative factors is significantly lower and represents average of 20 -30 %.

Agostino, Gagliardi and Trivieri (2011) discovered that bank concentration seems to positively (and significantly) affect SMEs default risk when credit relationships are very concentrated; that is when firms borrow heavily from their main bank and have few credit relationships with other intermediaries. A possible interpretation being that, as debt from the main bank increases and firms do not resort to multiple banking connection (in the attempt to induce competition among lenders), entrepreneurs might remain locked into lending relationships and so, become exposed to the potential negative effects of concentrated markets. The results suggest that a detrimental effect of bank market structure on firm default probability would emerge when lending relationships are highly concentrated, and it would be stronger the longer the duration of bank-firm relations.

Gambini and Zazzaro (2013, p. 1004) state that small firms maintaining a stable credit relationship with a main bank grow less than bank-independent small firms. This is especially true for small expanding firms, while for downsizing ones maintaining stable relationships with a main bank does not restrain their decline in employment and asset size. With regard to medium-large firms, results indicate almost the opposite. Long-lasting bank ties have a modest impact on growth performance of medium-large firms.

### 3 RESEARCH AIM, METHODOLOGY AND DATA

The aim of this article was to examine the relationship between personality characteristics and approach to the perception and management of credit risks. In this context there were examined the changes in the performance of SMEs, which occurred during the crisis, the knowledge of the credit request from the business, changes in the attitude of commercial banks to the SME segment, which occurred during the crisis and the perceived ability of the entrepreneurs to manage financial risks in their own company. These attributes have a significant impact on the intensity of the credit risk in the SME segment.

The research was conducted in selected regions of the Czech Republic and Slovakia through questionnaire investigation. A total of 449 owners of small and medium-sized companies have joined our research, of those 180 from Zlin region (Czech Republic), 164 from Žilina region (Slovakia) and 105 from the Trenčín region (Slovakia). Despite the fact that these regions belong to two different countries, they share many common characteristics, because they are neighbors with each other, have similar conditions for their development and intensively trade together. Therefore, it is assumed that this sample is homogeneous. The selection of respondents was conducted by a random selection and sample size is considered as representative enough. We have used the firm database Albertino and specialized software in this process.

Based on the preferred personal qualities and skills that were indicated in the questionnaire the entrepreneurs were classified into two categories, namely they are the artist-entrepreneur and entrepreneur-laborers, and there were also examined the differences in their entrepreneurial attitudes. Within the category of entrepreneur-artist there was included the owner of the company, which said in our questionnaire that the most important characteristics of an entrepreneur include at least two of the following (not to be afraid of risk, creativity, imagination, intuition and optimism). The total number of such respondents was 98. To the category of entrepreneur-laborers there was included an entrepreneur who has indicated the desired properties for making the business at least two of these options (perseverance, expertise, quality education, intelligence, responsibility, determination and patience). 351 of the entrepreneurs fell in this category.

The following hypotheses have been defined:

*H1: There are significant differences exist in the opinions of defined types of entrepreneurs to assess the performance of their companies.*

*H2: There are statistically significant differences exist in opinions of defined types of entrepreneurs in knowledge of lending criteria.*

*H3: There are statistically significant differences between the defined types of businessmen in assessing changes to the current approach of commercial banks in lending to SMEs in comparison to the pre-crisis period.*

*H4: There are statistically significant differences exist in opinions of defined types of entrepreneurs to manage financial risk in their companies.*

The associations in contingency tables were analyzed by Pearson statistics for count data. In the cases, where asymptotic requirements for the test were violated; series of 5000 Monte Carlo replications from original data has been conducted. P-value is being compared with standard 5% confidence level. P-value lowers than confidence level leads to rejection of the null hypothesis. The null claims there is no association between variables. Calculations have been performed in statistical packages XL Statistics and R. Also tools of descriptive statistics have been used such as: percentages and averages.

## 4 RESULTS AND DISCUSSION

In Table 1 there are presented the results of evaluation of decline of companies' performance by defined categories of entrepreneurs.

Tab. 1 – Evaluation of changes in the performance of firms by entrepreneurs-artists and entrepreneurs-laborers. Source: own research

<i>How has your performance changed in comparison to the pre-crisis period?</i>	Entrepreneurs-artists in %	Entrepreneurs-laborers in %	p-value
1. Decreased significantly (more than 20 %)	21.59	27.35	0.27134
2. Slightly decreased (to 20 %)	37.50	35.33	0.70394
3. Is stabilized	17.05	22.51	0.26272
4. Increased slightly (to 20 %)	15.91	9.97	0.11410
5. Significantly increased (more than 20 %)	4.55	2.56	0.32708

The values of the test criteria have confirmed that the changes performance evaluation of enterprises according to defined parameters is very similar and statistically significant differences in the responses have not been found. The Hypothesis 1 was rejected.

Both groups rate market risk as the most important risk, which was demonstrated by a decline in performance of companies during the crisis, because up to 59% of entrepreneurs-artists and 63% of entrepreneurs-laborers in our research have stated that the performances have dropped.

Our results are compatible with the findings of other studies. According to Fetisovová et al. (2012) the financial and economic crisis has had serious implications on the performance of small and medium-sized companies in the European Union. In 2009, the gross production of SMEs within the EU27 decreased by 5.5%. Insufficient effective demand was the most urgent issue for 29% of these SMEs. The authors report that the demand in the domestic markets of the EU27 will remain weak. In this context Clowes and Bilan (2014) state that the Czech Republic, the country endowed with greater shares of capital in production (compared with Poland, Hungary and Romania) was not immune to the recession, as confirmed by the results of our research. In this context Knápková, Homolka, and Pavelková (2014) emphasize the importance of advanced techniques of the financial management in the Czech companies in the current economic environment.

A particularly important problem of SMEs is a financial gap since many of these companies have limited access to external financial sources. Even before the economic downturn, some small businesses were having trouble accessing the funds necessary for growth and innovation. As a consequence of the financial crisis, banks in many countries are even less willing to lend to businesses, which further escalates the problems faced by companies. (European Commission, 2011). According to Fetisovová et al. (2012) the approach to financial resources for SMEs represents a serious problem for SMEs. However, in the short term, it is less urgent than the lack of demand on domestic markets.

In our research, there was also compared the risk assessment from the regional perspective. It was found out, that entrepreneurs in Zlin region and entrepreneurs in Zilina and Trencin regions assess the risks very similarly. The only exception were the differences in the safety risk assessment, where entrepreneurs in Zilina region statistically significantly more perceived

the effect of this risk in comparison with the businessmen from Zlin region. (Belás et al., 2014)

It could therefore be assumed that the current assessment of business risks, which was found out through our own research in the segment of SMEs in the analyzed region is relevant: the most significant risk to the SME segment is a market risk, followed by financial risk. This assessment is not dependent on regions and neither from the defined categories of entrepreneurs.

In Table 2 there are given results of knowledge of commercial banks' lending criteria.

Tab. 2 – Knowledge of lending criteria of banks by the entrepreneurs-artists and entrepreneurs-laborers. Source: own research

<i>Do you know the criteria which banks assess in their lending process?</i>	entrepreneurs-artists in %	entrepreneurs-laborers in %	p-value
1. Yes	55.68	38.00	0.00262
2. No	10.23	15.14	0.23800
3. I have some idea	34.09	46.86	0.03078

The Hypothesis 2 was confirmed. It was identified that there exist statistically significant differences in opinions of defined types of entrepreneurs in the knowledge of lending criteria. The entrepreneurs-artists statistically significantly more stated that clearly aware of commercial banks' lending criteria in comparison with the entrepreneurs-laborers (p-value=0.00262), while at the same time statistically less was received an answer: I have some idea (p-value=0.03078).

It could be agreed with Behr and Güttler (2007), who see the solution on companies' part that understood banks' approach within the evaluation of creditworthiness and also they were able to evaluate their expected probability of default (PD) using rating model. This fact could help firms to understand their position from the bank's position. Also this fact would lead to provide necessary document about themselves for better assessment of their creditworthiness and also it would lead to the possibility of further negotiations between the bank and the company about credit conditions. According to author, knowledge of own PD also allows to increase transparency in credit process. As well as it allows potential use for searching of external funding sources. If SMEs have knowledge about their creditworthiness, they may affect management decisions in favor of new sources of external funding due to the expanding range of financing options.

Tab. 3 – Evaluation of the changes of approach of commercial banks to finance SMEs during the crisis. Source: own source
